How lethal injection is the best way to tackle Japanese knotweed – one of the most invasive weeds you will come across

Invasive weeds are damaging and difficult to control but Japanese knotweed, the general name given to a group of species belonging to the genus Fallopia (family Polygonaceae), and native to Japan and parts of China, stands head and shoulders above the rest. In their native Asian range they are primary volcanic colonisers and generally far less vigorous compared to Japan and parts of China, stands head and shoulders above the rest. In their native Asian range they are primary volcanic colonisers and generally far less vigorous compared to

The introduction of Japanese knotweed as an ornamental plant into early Victorian gardens must have seemed like a good idea at the time but it has left a huge and growing weed legacy. Capacity for vegetative spread in situ through enormous fast growing and resilient rhizomes, made easier by the very nature of its favoured riparian and urban environments, is the secret of Japanese knotweed’s success. Dense growing stands restrict access for riverbank inspections and increase flood risks through large quantities of dead stems and leaves washed into rivers and streams. Attempts to remove established stands from riparian areas can cause instability in river banks and increase the risk of soil erosion. Urban site infestations cause considerable damage to hard surfaces. With stems than can penetrate concrete tarmac, there is no barrier to Japanese knotweed. The severity of Japanese knotweed is clear to see from the legislation used to limit spread and damage. It’s scheduled under the 1981 Wildlife and Countryside Act, making it an offence to plant or cause it to grow in the wild. It is also classified as ‘Controlled Waste’ under the Environment Protection Act (1990) and must be disposed of on a licensed landfill site in accordance with the Environment Protection Act (Duty of Care Regulations 1991).

A multi-faceted weed

Red-coloured, spear-like aerial shoots emerge in spring - reaching 30cm by April and forming a massive foliar canopy two to three metres tall by summer’s end. Plants produce large numbers of white flowers in summer but rarely any viable seed, probably due to UK climatic restrictions on sexual reproduction. New shoots arise from the tiniest pieces of rhizome and cut stems - even during the only ‘knotweed-free window’ during late autumn and winter. Dead stems and leaves decompose very slowly to form a deep litter that prevents the germination of other seeds. Failure to produce viable seed is more than compensated for by a fast growing and robust system of rhizomes allowing Japanese knotweed to exploit and dominate environments through vegetative propagation.

Rhizome systems may extend up to 7m from the parent plant and to a depth of 3m. Rhizome fragments as small as 0.7g can generate new plants and pieces of fresh aerial stem will grow shoots and roots in soil or water. Plants achieve up to 3m of aerial growth and 6m of rhizome growth in a single growing season. New shoots arise from the tiniest pieces of rhizome and cut stems - even during the only ‘knotweed-free window’ during late autumn and winter. Dead stems and leaves decompose very slowly to form a deep litter that prevents the germination of other seeds. Failure to produce viable seed is more than compensated for by a fast growing and robust system of rhizomes allowing Japanese knotweed to exploit and dominate environments through vegetative propagation.

Knotweed produces lots of flowers (underground stems) are so fast growing, all pervading and consuming that nothing else stands a chance - even during the only ‘knotweed-free window’ during late autumn and winter. Dead stems and leaves decompose very slowly to form a deep litter that prevents the germination of other seeds. Failure to produce viable seed is more than compensated for by a fast growing and robust system of rhizomes allowing Japanese knotweed to exploit and dominate environments through vegetative propagation.

As long as it is in contact with water, Japanese knotweed using strimmers, flails or diggers can aggravate spread. Herbicide application

Application of herbicide is the only sure and safe way to manage Japanese knotweed but this is easier said than done due to the sheer size and resilience of its rhizomes. A number of herbicides are effective against Japanese knotweed but by how much and for how long depends on the application technique used. Application technique will ultimately determine the success of chemical control against Japanese knotweed.

Spaying with contact herbicide will burn off the leaves but rhizomes survive and produce new stems. The only sure and safe way to dispatch Japanese knotweed is by placing a systemically acting herbicide (most usually glyphosate) into the plants by injection of intact stems low down and at the most appropriate time of the growing season.

Target area is the lower part of the aerial stem to minimize the distance for downward translocation into the rhizome system. Best time is

How lethal injection is the best way to tackle Japanese knotweed – one of the most invasive weeds you will come across

Japanese knotweed continues to destroy ecosystems and urban infrastructure and is one of few herbaceous weeds requiring direct placement of herbicide inside the plant to ensure quick complete control.

The introduction of Japanese knotweed as an ornamental plant into early Victorian gardens must have seemed like a good idea at the time but it has left a huge and growing weed legacy. Capacity for vegetative spread in situ through enormous fast growing and resilient rhizomes, made easier by the very nature of its favoured riparian and urban environments, is the secret of Japanese knotweed’s success.

Dense growing stands restrict access for riverbank inspections and increase flood risks through large quantities of dead stems and leaves washed into rivers and streams. Attempts to remove established stands from riparian areas can cause instability in river banks and increase the risk of soil erosion. Urban site infestations cause considerable damage to hard surfaces. With stems than can penetrate concrete tarmac it’s no barrier to Japanese knotweed. The severity of Japanese knotweed is clear to see from the legislation used to limit spread and damage. It’s scheduled under the 1961 Wildlife and Countryside Act making it an offence to plant or cause it to grow in the wild. It is also classified as ‘Controlled Waste’ under the Environment Protection Act (1990) and must be disposed of or a licensed landfill site in accordance with the Environment Protection Act (Duty of Care) Regulations 1991.

A multi-faceted weed

Red-coloured, spear-like aerial shoots emerge in spring - reaching 30cm by April and forming a massive foliar canopy two to three metres tall by summer’s end. Plants produce large numbers of white flowers in summer but hardly any viable seed, probably due to UK climatic restrictions on sexual reproductive development.

Above ground stems die back and dry out in autumn, but overwintering rooststock and rhizomes (underground stems) are so fast growing, all pervading and consuming that nothing else stands a chance - even during the only ‘knotweed-free window’ during late autumn and winter. Dead stems and leaves decompose very slowly to form a deep litter that prevents the germination of other seeds.

Failure to produce viable seed is more than compensated for by a fast growing and robust system of rhizomes allowing Japanese knotweed to exploit and dominate environments through vegetative propagation.

Rhizome systems may extend up to 7m from the parent plant and to a depth of 3m. Rhizome fragments as small as 0.7g can generate new plants and pieces of fresh aerial stem will grow shoots and roots in soil or water. Plants achieve up to 3m of aerial growth and 6m of rhizome growth in a single growing season.

New shoots arise from the tiniest pieces of rhizome and cut stem-sections will root at the nodes. Crown can survive drying or composting to produce new canes once in contact with water. Attempts to mechanically control Japanese knotweed using strimmers, flails or diggers can aggravate spread.

Herbicide application

from late summer through autumn when rhizomes become sinks for soluble food and nutrients which is translocated downwards from the leaves before these senesce and fall off. Injected systemic herbicide is subject to this same strong basipetal (downward) translocation into the rhizome system which is subsequently killed.

**Death by lethal injection**

Japanese knotweed’s hollow stem is its ‘Achilles Heel’. Professional stem injection applicators designed and dedicated to control of hollow-stemmed weed plants such as Japanese knotweed are available.

Stem injectors used to control Japanese Knotweed include:
- 'Injectordos' from Micron Sprayers at Bromyard, Herefordshire.
- 'JK Injection Tool' from Stem Injection Systems at Stockport, Cheshire
- 'Stem Master' from Nomix Enviro at Andover, Hampshire.

The advantages offered by the stem injection technique focus on effectiveness, ease of access and use and all round safety for operators and the environment.

Use of these relatively lightweight and small applicators mean operators can access and treat the most dense stands of Japanese knotweed. By providing a closed delivery system the technique can be safely and effectively used at any time including during rainfall. The closed highly targeted delivery system means there is no danger of product escaping into the environment to damage nearby plants.

Also, by delivery of a measured dose into the hollow stem, the injection technique can usually achieve ‘death by lethal injection’ in one application.

Stem injection does a truly ‘inside job’ on Japanese knotweed and is used with good effect on other invasive weeds such Himalayan balsam and Giant Hogweed which also have hollow stems. Stem injection in something most golf courses can carry out using their own resources.

However, taking into account equipment, expertise and safety – including the need for an appropriate operator’s licence if application is made near water – then employing the services of a specialist company advertising this expertise may turn out to be the most convenient and effective option.

---

**Complete Weed Control offers a specialist contract service for the eradication of all problem weeds, wherever they appear including:**

- Total weed control - Hard, soft and gravel surfaces
- Selective weed control – For control of broadleaf weeds in grass
- Aquatic weed control – Marginal, submerged and floating weeds
- Chinese control – In turf, plants and trees
- Grass growth control – Retardation of grass growth in all areas
- Insect control – In turf, plants and trees
- Fertilizer application – Liquid or granular
- ‘Moss & algae control’
- ‘Worm control’ – In all grassed areas
- ‘Frowary’ – Tree planting, bracken control and insectsides

Experience plays a major factor in successful treatment. Knowing when and how to apply the appropriate product can speed up eradication and save time and money. All work is undertaken adhering to strict health & safety guidelines.

**about the author**

**Dr Terry Mabbett**

Dr Terry Mabbett is a disease, pest and weed control specialist with forty years international experience covering research, advisory and journalism. His current focus is professional turf and alien insect pests and pathogens of Britain’s native and naturalised trees.

**Complete Weed Control**

Complete Weed Control are proud of the fact that for the last 40 years we have offered a specialist contract service for the eradication of all problem weeds.

Our clients include government departments, local authorities, public utilities, golf courses, amenity areas as well as commercial sites.

For a complete solution, call the largest established amenity weed control company in the UK and Ireland.

**The complete solution...**

Complete Weed Control offers a specialist contract service for the eradication of all problem weeds, wherever they appear including:

- Total weed control – Hard, soft and gravel surfaces
- Selective weed control – Control of broadleaf weeds in grass
- Aquatic weed control – Marginal, submerged and floating weeds
- Disease control – In turf, plants and trees
- Grass growth control – Retardation of grass growth in all areas
- Insect control – In turf, plants and trees
- Fertiliser application – Liquid or granular
- Moss & algae control
- Worm control
- Pest control
- Moisture control
- Herbicide treatment

Experience plays a major factor in successful treatment. Knowing when and how to apply the appropriate product can speed up eradication and save time and money. All work is undertaken adhering to strict health & safety guidelines.
