There has been an extensive development of commercial seed production of Seaside creeping bent and various colonials such as Astoria and Highland from predominately native stands. Although some differences of opinion still exist concerning the relative merits of the vegetative versus seeded, and creeping versus non-creeping, the greater weight of opinion and experimental evidence overwhelmingly favors the vegetative, creeping types.

As early as 1921, Piper and Oakley reported that vegetative creeping bent is “all in all, the best of putting green grasses”. This has been further substantiated by the later work of the USGA Green Section, various experiment stations and performance on many courses.

**Significant Improvement**

Practically all improved vegetative strains were isolated following years of natural selection under actual playing conditions of early mixed seeded types such as South German bent. Undoubtedly, the continuous use of this technique has resulted in a very significant improvement in the quality of turf over the years. We need only to compare the present day performance of our “named strains” versus the old Virginia, Columbia and Washington, or with the turf produced with commercially available seed to appreciate what has been accomplished.

What are the limitations and problems with the vegetative bents?

Being confined in germ plasm these strains are limited to “optimum” performance to local regions of adaptation. Original selection and proper testing have been limited to a rather small section of the country, yet the strains have been used quite extensively at the larger fringe areas.

**Documented Evidence Lacking**

Within a region of proved adaptation the performance of these strains may vary significantly from year to year due to fluctuations in climatic conditions. Even more pronounced may be the use, management and growing environment to which they are subjected. Documented evidence in differential wearing ability, nutrient requirements and other specific management practices is practically non-existent. As a result, it may take a quarter of a century before the relative merits of a single strain are recognized.

Lacking certification and proper handling, many cases of lost identity have re-

*(Continued on page 96)*
Vegetative Bent
(Continued from page 58)
sulted from the hand-me-down type of
distribution which has been so prevalent
with vegetative strains.

Many new greens have been seeded to
common quality bents because the better
vegetable strains were not available for
planting. In other cases $150 worth of
seed appeared many times cheaper than
the outright purchase of stolons for plant-
ing an entire course's greens. Another
common problem, unfortunately, is when
the decision on what to plant is made by
the unqualified or the uninformed.

Widest Adaptation Range
Based on practical use observations,
Congressional bent appears to possess the
widest range of adaptation of the vege-
tative strains. Cohansay stands out in the
higher temperature regions, whereas the
older Washington strains appear best
adapted in cooler areas where dollarspot
prevails as the major disease. The velvets
are definitely limited to New England
and in the Midwest we see the best adap-
tation of Old Orchard, Collins and
Toronto.

The seeded Seaside gives its best ac-
count in less humid areas where diseases
are definitely less prevalent. One can also
find satisfactory greens of Seaside where
natural selection has eliminated the weak-
er types over a period of years. In these
cases we must also recognize the effi-
ciency of individual supts. as a determin-
ing factor.

Best of Seeded Strain
The first departure from the relatively
simple method of selection has been the
synthetic or polycross approach used by
Musser to develop Penncross seeded bent.
This consisted of using one of the system-
ic methods of breeding that is available
to plant breeders. Objectives of this pro-
gram were to produce a superior seeded
bent and to overcome some of the very
apparent limitations of vegetative strains.

Practical experience is now confirming
experimental results which showed that as
a synthetic with a broad gene-base, Penn-
cross would perform over a much wider
region than a single strain. It will pro-
duce significantly better turf than any
other presently available commercial seed-
ed bent, and it will compare very favor-
ably with the better vegetative strains in
most areas, and surpass others in fringe
areas. However, it is not a supergrass and
requires good sound management just as
Now—your choice of 3 great range balls

BY WORTHINGTON

Now you can select the range ball that best suits the needs of your range!

1. New Paintless Yellow
Golden yellow color gives better night visibility. Lively, yet tough as nails! No re-painting—wash and it’s bright as new.

2. Paintless White
Operators call it the most rugged ball ever developed. Eliminates re-painting. A choice of color stripes.

3. Luster-White Painted
A favorite with range operators. Lively! Extra-tough vulcanized cover with a new polyurethane finish that stays gleaming white for the life of the ball.

All range-proven for years—guaranteed never to go out of round, or explode under scorching summer sun. Imprinted with your range name in big, bold wrap-around letters—up to 14 letters and spaces on each side of the ball. Choice of color bands, too.

For full details call your Worthington Representative now, or write WORTHINGTON GOLF INC., ELYRIA, OHIO.

Worthington

Premier name in golf ball developments since 1904.

Fairways: Orphans of Course

Fairways continue as the chronic overall problem. Many retain the designation of 25 years ago as being “the orphan” of the golf course. The most plausible explanation appears to be the non-existence of grasses capable of satisfactory performance under the level of management given fairways. The problem is most perplexing with the cool season grasses, especially in the crabgrass belt.

Bluegrass can’t be held on close-cut, watered fairways, especially when weakened by diseases, high temperature and excessive water. At best, its density leaves something to be desired. Fescue is even less adept under these conditions.

Introduction of leafspot resistant Merion was looked upon as a major development for both irrigated and non-irrigated fairways. Although it was formally released 13 years ago, we have yet to see exactly where it fits into our region of adaptation picture.

Merion will provide a tight, dense turf when adequately fertilized. It tolerates reasonably close clipping due to its decumbent growth habit. Its overall average performance is definitely superior to common and other current bluegrass varieties. However, diseases may still be a major problem in some areas, especially when the grass is subjected to excessive water or low fertility.

Accumulate Thatch

Older stands of Merion show a tendency to accumulate a heavy thatch layer. Thatch will always be a problem with any vigorous grass, stoloniferous or rhizomatous, and must be contained by good management.

Our most promising approach in the near future with the bluegrasses is a seed mixture of improved types. Individual strains will have to be compatible in germination, seeding vigor, general vigor and fertility requirements. Similar texture and color are desirable but not an absolute necessity.

Creeping bent is impractical on large fairway areas due to its growth characteristics and demands. Vigorous growth during favorable conditions quickly results in a spongy, thatched sod which perpetuates its high susceptibility to many diseases and insects.

Colonial May be Useful

Colonial bent, though, offers hope for irrigated fairways in cooler areas. High leaf density and rapid growth permit any other type of grass.

quick recovery from injuries and makes them tolerant to close mowing. Colonials do not thatch as readily as the creepers.

Most commercial seed is contaminated with creepers and susceptibility to disease, especially brownpatch. It must be realized that no improved types exist and our knowledge of the species is limited.

U-3 Bermuda and Meyer zoysias are now being accepted as a practical approach toward solving the perplexing question of fairway and tee grasses in the 'no man's land' area between our northern and southern climatic zones. The decision was undoubtedly reached only after a fair trial was given to these grasses, and due credit must be given to those individuals who pioneered the effort by abiding by the principles of good turf management and rational thought. Trials consisting of "just plugging these grasses and waiting to see what happens" contributed very little practical information.

**Musser Text Revised**

"Turf Management," has been revised and brought up to date by its author, H. B. Musser, professor emeritus of Pennsylvania State University. It soon will be published by McGraw Hill Books, Inc., for the USGA green section.

**Ryder Cup Matches**

The 1961 Ryder Cup matches will be played over Royal Lytham and St. Anne's, St. Anne's-by-the-Sea, Eng., Oct. 13-14. This will be the 14th meeting of PGA teams representing U. S. and Great Britain.
