The role of guttation fluid in fungal disease development.

The objective of this study was to ascertain the relationship of guttation to the spread of turfgrass diseases by (a) fungal thread and (b) spores. Guttation fluid was collected in early morning. Drops of guttation fluid and water were placed on seaside bentgrass leaves and fungal threads of dollar spot and brown patch were added to the droplets. Actual infection occurred only with the droplets containing the guttation fluid.

In a related study, guttation of moistened four-inch plugs of turf was induced by placing the plug in a closed plastic bag. Fungal threads of brown patch were placed on a single leaf. In this situation, the fungal threads were observed to bridge from one guttation droplet to another with mycelial growth being stimulated from each droplet.

Studies were also conducted with leaf spot which spreads by spores. Spores suspended in guttation fluid and water were sprayed on bentgrass seedlings. All plants sprayed with the spore-guttation fluid were dead after six days. All plants sprayed with the spore-water suspension survived even after 14 days. The guttation fluid induced acceleration and increase in spore germination, percentage of infections and the subsequent development and spread of the fungus in the infected tissues.

Comments—Droplets of water occur at the leaf tips of turfgrasses during the night and early morning hours. These droplets are produced by guttation or may be the result of direct wound exudation from the freshly cut leaf. Leaf exudations should not be confused with dew, which is more likely to be distributed over the leaf rather than at the tip. Rapid water absorption by roots, restricted transpiration, frequent irrigation, close-frequent mowing and heavy nitrogen fertilization will stimulate leaf exudation. Exudation fluids enhance turfgrass disease spread and infection because of the mineral salts, sugars, amino acids, amides and other organic acids contained in the exudate.

Since leaf exudates enhance disease activity, it is a desirable practice to break up or remove these droplets. The preferred method of exudate removal is by syringing, since the water washes the disease-favoring organic material from the leaf surface. Dragging, brushing or poling are also effective in disrupting the droplets and increasing evaporation. However, the latter methods may also tend to distribute the fungal threads over the entire leaf surface. Leaf exudation can be minimized by effective air movement and avoiding excessive nitrogen fertilization or watering.

Recent advances in controlling winter injury of turfgrasses.

Turf heating with electrical cables has ensured the winter survival of non-hardy turfgrasses on greens at Lethbridge, Alberta, Canada. Turfs maintained at minimum temperature of 38 to 42° F. showed injury and had an uneconomical power requirement. On the other hand, turfs held at a minimum temperature of 26 to 32° F. survived the winters in good condition and had an economical power consumption. The results indicate that the power requirement to bring non-hardy turfs through the winter uninjured was in the economical range.

Polyethylene covers are also being evaluated for use in winterkill prevention caused by desiccation and low temperature. Studies in southern Alberta indicate that polyethylene covers increase the effectiveness of inorganic mercurial fungicides used in the control of snow mold. One half the recommended rate for mercurial fungicides was effective in the control of snow mold when the turf was covered immediately after application of the fungicide. Problems were encountered in securing the cover to the ground. In addition, the covers had to be removed at intervals during the spring in order to mow the excessive leaf growth.

Tests at Edmonton and Lethbridge showed most creeping bentgrasses to be more winter Hardy than colonial bentgrass and annual bluegrass. Northland creeping bentgrass has exhibited superior winter hardiness to low temperature and snow mold.

Comments—Electrical heating of golf greens and tees is still in the experimental stage of development in North America. Soil warming shows promise for future use on courses having medium high to high budgets. This technique may offer
**BEARD Continued from page 18**

a means of providing frost free turf throughout the year. Also, spring green up will be earlier.

An evaluation of high temperature effects on annual bluegrass. (*Poa annua L.*)

J. A. Fischer, Master of Science Thesis. Michigan State University, pp. 1-42, (from the Department of Crop Science, Michigan State University, East Lansing, Michigan 48823.)

The effects of high temperature on *Poa annua* were studied in a specially designed wind tunnel chamber. Wind speed in the chamber was 11.4 mph and the relative humidity approximately 100 per cent. The temperature treatments ranged from 98 to 112° F. with exposure times varying from ten minutes to twelve hours. Injury was evaluated by grass observations and a histological technique.

High temperature resulted in a systematic injury to the *Poa annua* plant tissue. Injury occurred first at the junction of the leaf sheath and the leaf blade of all affected leaves. The root crown tissue, the youngest leaf and the apical meristem, in that order, were the least susceptible to lethal high temperatures. Exposure to high temperature hastened aging of leaves. The order of cellular changes observed was protoplasmic granulation, protoplasmic coagulation, cell wall breakdown, and total cell collapse.

At any one temperature treatment the degree of kill increased proportionally with exposure time. Kill of *Poa annua* at 100 per cent relative humidity occurred after only one hour exposure to a temperature of 106° F.

Comments—Direct high temperature kill of *Poa annua* was observed to occur at surprisingly low temperatures. Temperatures of turfs in the 104 to 108° F. range occur under field conditions. Turf-
You could use this little fellow (and gal all in one!) to maintain your turfgrass... but we don't advise it, not if you like your job!

The fact is... earthworms alone can't do the job of maintaining your turfgrass area in tip-top shape. The only way you can be sure you are doing the best possible job is to use WEST POINT PRODUCTS turfgrass equipment... the BEST you can buy for fast, trouble-free turfgrass care and renovation. After all, WEST POINT has been designing and building the BEST for over twenty years!

Get the latest facts on how you can do a better job of maintaining your greens, tees, and fairways. Clip and mail this coupon for information on any (or all) of these quality WEST POINT grounds maintenance units:

WEST POINT PRODUCTS CORP.
West Point, Penna. 19486

- Please send facts on:
  - AERIFYING (opens and loosens soil without disturbing the grass)
  - CORING/CLEANING (core and clean in one operation)
  - VERTICAL MOWING/THATCH REMOVAL (vertically mow, remove thatch, and clean area in one operation)
  - TOP DRESSING (top dress soil surface, not the grass)
  - MORE MAN-HOURS FOR LESS MONEY (the MINI-TRUCK® grounds maintenance personnel/cargo carrier vehicle puts wheels under your men, cuts maintenance costs, pays for itself in one year)
  - ALL LITERATURE

Please arrange for no-obligation demonstration

men should recognize that it is the plant tissue temperature and not the air temperature that is critical. Actually, a high soil temperature is a more valid indicator of potential high temperature injury than high air temperatures.

These data suggest that high temperatures may cause a greater portion of the mid-summer death of Poa annua than has been thought in the past. Plants under a water deficit are more susceptible to low temperature kill. Proper water management, good air movement and a healthy turf are important factors that will increase the tolerance of turfgrasses to high temperature.

Early growth of annual and perennial ryegrass.

Two stages of early growth were observed for annual ryegrass (Lolium temulentum) and perennial ryegrass (L. perenne). The first stage encompasses the initial nine days following seeding when the growth rate is extremely rapid. Annual ryegrass had 90 per cent germination in 48 hours while perennial ryegrass had 80 per cent germination after four days at 68° F. The second state, which may be indicative of the rest of the growing season, is one of slower growth. Annual ryegrass had a larger root system and a higher respiration and photosynthetic rate.

Comments—This paper emphasizes the superior establishment vigor of the ryegrasses, with annual being more vigorous than perennial. The rapid establishment is valuable where a quick, temporary cover is desired. This attribute is desirable when planting on steep slopes having a high erosion probability and when conditions for germination are inadequate due to moisture stress.

An undesirable aspect of such rapid establishment is excessive competition to the more desirable, permanent species contained in the mixture. It can be especially det-
INCREASE EARNINGS, SERVICE & SPACE
Remodel your present storage space, bring your bag racks up to date
WITH NEW Stafford VERTICAL BAG RACKS

U.S. & CANADIAN PATENTS

Your members will like the extra convenience and care. Your pro shop profits from 40% more space these racks make available.

Double unit shown holds 16 bags, size 2' x 4' x 6'-3" high, gives 12" x 12" space for bags. Single unit holds 8, size 1' x 4' x 6'-3" high. Sturdy steel. Bags set solid on tapered shelves.

- Wear and tear of golf bags is completely eliminated
- Damp bags dry faster — no mildew
- Provides a neat appearance
- Faster, easier storage
- Easy to install and add more as needed —

Send us your floor measurements, we will plan a layout and quote you — no obligation.

rimentoj to Kentucky bluegrass and red fescue, which can be almost crowded out. The competition is most severe for light with the quicker germinating species shading the slower germinating grasses.

Sixteen bermudagrass varieties were overseeded using the following: (a) roughstalk bluegrass (Poa trivialis) at six pounds per 1,000 sq. ft., (b) Pennlawn red fescue (Festuca rubra) at six pounds per 1,000 sq. ft., (c) annual ryegrass (Lolium multiflorum) at 15 pounds per 1,000 sq. ft., and (d) a mixture of Highland bentgrass, Pennlawn red fescue, and Kentucky bluegrass at 10 pounds per 1,000 sq. ft. The bermudagrass was maintained at 3/4 inch. In November the seed was applied, the area renovated with a vertical mower leaving the debris as a mulch, and irrigated. All four seed sources had excellent initial stands.

In early February, thinning in stands of the overseeded turfs became evident. Stand data was taken on February 18 and March 14. The stands for roughstalk had the highest density followed closely by Pennlawn red fescue. The densities for annual ryegrass and the mixture were significantly less. From February 18 to March 14 the roughstalk bluegrass density remained constant, while the other three overseeding treatments increased in stand density.

The bermudagrass varieties varied in their response to overseeding by certain grasses. These differences must be recognized in evaluating overseeding practices. Stands from overseeding were significantly lower for Tifway, Ormond, and Tiflawn bermudagrass varieties. Stands were quite high for Arizona Common, Midway, and Tifcote.

Discover America.
It's 3,000 smiles wide.

See exotic sun-bronzed girls on tropical beaches.
Follow challenging trails up snow-bound peaks in the dead of summer.
Uncover centuries of secrets buried in strangely beautiful caverns.
Delight in authentic native dances: the boogaloo, the shing-a-ling, the skate.
 Everywhere you go, friendly natives will introduce you to their strange folkways: the single-minded cult of the surfer, the infinite imagination of the city-dwellers.
America is action, ideas and a million surprises.
Isn't this the year to get out and discover it for yourself?
A comparison of colonial and creeping bentgrasses for 1/2- and 3/4-inch turf.

The objective of this study was to compare the performance of colonial and creeping bentgrasses when mowed at fairway mowing heights. Five colonial bentgrasses (Astoria, Exeter, Highland, New Zealand browntop, and R. J. colonial) and four creeping bentgrasses (Arlington, Dahlgren, Penncross and Seaside) were maintained at cutting heights of 1/2 and 3/4 inches. Also included were two nitrogen treatments: two and four pounds of nitrogen per 1,000 square feet per year. There were a maximum of four irrigations per year with no fungicides applied. The length of the experiment was eight years.

For the first five years, the creeping bentgrasses ranked higher in turfgrass quality than the colonial bentgrasses. This advantage decreased after seven years. The advantage of the creeping bentgrasses was more apparent at a 1/2-inch cut than at 3/4-inch. The incidence of dandelions and annual bluegrass was less in the creeping bentgrasses than in the colonial types.

Thatch accumulation was greater at the higher (3/4 inch) and nitrogen level (four pounds nitrogen). The thatch accumulation was greater with the creeping bentgrasses, but it did not appear to offer unusual increases in trouble through eight years. The greater thatch accumulation was attributed, at least partially, to the greater natural density of growth of the creeping types.

Dollar spot incidence resulted in a late summer and early fall slump in turf performance greater in the creeping bentgrasses than in the colonials. Dollar spot infestations were greater at the lower cut.

A comparison among the seven bentgrasses showed Arlington to give the best performance under fairway management and New Jersey conditions. Seaside showed no advantages over the colonial bentgrasses. In spite of the high cut and vigorous growth characteristics, Penncross had good overall quality. Among the colonial bentgrasses, Exeter and R. I. colonial had a decided advantage. At the 3/4-inch mowing height all the bentgrasses except Seaside, Arlington, and Penncross had good dollar-spot resistance.

Comments—These results indicate that some creeping bentgrass selections are just as desirable as the colonial types for use under fairway management. The creeping types have a greater thatching tendency but also have a greater density of growth and thus can compete more favorably against invading weeds such as Poa annua. The net result is better quality. One should not conclude from these
results that all creeping bentgrasses are desirable for fairways. Certain creeping bentgrasses thatch excessively and/or have a high susceptibility to certain turfgrass diseases. These characteristics are not desired in a bentgrass for fairway use.
