G-91 Red • Green • Black

Colorful Hole Numbers, attractively designed in two exciting styles. On strong 18 gauge steel, with weatherproof baked enamel finish . . .size 12” x 18”. Just send us your scorecard, with correct yardage, indicate style wanted and we will custom make in just three weeks! Sturdy 5½’ channel posts $1.50 each.

Send check with order and we pay shipping charges.

Nutritional Requirements of Poa Annua L.

The objective of this study was to determine the effect of nitrogen, phosphorus, potassium and soil pH on the growth of annual bluegrass roots and shoots. It was conducted under greenhouse conditions with the annual bluegrass plants maintained at a cutting height of 1.5 inches. Two levels of nitrogen, phosphorus, potassium and lime were incorporated into the root zone of two soils, a loamy sand and a silt loam. Data collected included the amount of shoot growth, weight of crowns, amount of roots produced and the number of seedheads formed.

The higher level of nitrogen fertility stimulated shoot and root growth to the greatest extent followed by the higher level of phosphorus. Potassium had very little

Continued on page 24
effect on the rate of shoot growth. Growth was more favorable when a balance in the levels of nitrogen, phosphorus and potassium was utilized. Shoot growth of annual bluegrass was greater at a soil pH of 6.5 compared to 4.5. Seedhead production was less at a soil pH of 4.5 than at 6.5.

The authors concluded that annual bluegrass can produce more acceptable growth under relatively infertile soil conditions compared to Kentucky bluegrass. However, annual bluegrass is responsive to increased levels of fertility or higher pH levels, particularly on poor, coarse textured soils.

Comments: One approach to controlling weeds is the modification of cultural practices, such as fertility and pH, to the extent that conditions are unfavorable for growth of the weed. The results of this study indicate that control of annual bluegrass by manipulation of the soil pH or the nitrogen, phosphorus and potassium fertility levels is not promising since the optimum levels for growth are quite similar to the optimums for the desirable species. It should be indicated that there are other cultural practices which influence annual bluegrass growth and competitive ability substantially. For example, (a) frequent or excessive irrigation or (b) a close cutting height will favor annual bluegrass growth.
