Identifying Agrostis cultivars

The objective of this study was to develop methods for distinguishing species and cultivars of Agrostis while in the seedling stage. The studies were conducted in controlled climate growth chambers with continuous light with a complete nutrient solution supplied. The experiments were terminated five weeks after the grass seeds were planted. The data collected included growth habit, leaf sheath color, stem diameter, leaf blade length, leaf blade width, stem length and stem number. Cultivars evaluated in the study were common redtop (Agrostis alba L.), ‘Kingston’ velvet bentgrass (Agrostis canina L.), ‘Penncross’ and ‘Seaside’ creeping bentgrasses (Agrostis palustris Huds.) and ‘Exeter’ and ‘Highland’ colonial bentgrasses (Agrostis tenuis Sibth.).

Differences among species were evident within three weeks following planting. Creeping bentgrass plants were characterized by long stems, an intermediate leaf size and a prostrate or decumbent growth habit. Velvet bentgrass plants had small leaves, many stems, a small stem diameter and a prostrate or decumbent growth habit. Colonial bentgrass plants were short, intermediate in leaf size and upright in growth habit. Redtop plants were characterized by a large leaf size, relatively few stems, a large stem diameter and an upright growth habit.

A comparison between the two colonial bentgrass cultivars, Exeter and Highland, showed Exeter to have twice as many leaf sheaths with a red coloration as was observed with Highland. The Highland cultivar had a greater number of stems per plant, a greater stem length and a significantly higher percentage of decumbent plants. In contrast to the differences observed between the two colonial bentgrass cultivars, no significant differences were observed between seedlings of the two creeping bentgrasses.

Seed analysts can identify most Agrostis turfgrass seed as to species but distinguishing cultivars is much more difficult. The authors have concluded from this study that Agrostis species and certain cultivars can be distinguished in the seedling stage. Thus, such a technique could be used to determine if seed of certain species is correctly labeled as to the specific cultivar.

The objective of this study was to determine the optimum light intensity for turfgrass growth and development as affected by two types of light quality: (a) blue, with sunlight transmission primarily in the 410 to 510 millimicron range and (b) gray, with sunlight transmission from 390 to 760 millimicrons. Mature sods of Tifgreen bermudagrass and Windsor Kentucky bluegrass were utilized in this study. The cultural practices included a weekly clipping at 1.5 inches, watering three times per week and a monthly application of one pound of actual nitrogen per 1,000 square feet. The sod pieces were placed under transparent, acrylic plastic panels having varying light transmission properties in the blue and gray light transmission ranges. The light intensities used in the study ranged from 18 to 74 per cent of full sunlight for the blue transmitted light treatment and from 15 to 71 per cent for the gray treatment.

mitted light. Data taken include fresh weight of clippings removed and plant height, plus visual ratings of turfgrass quality, color, shoot density, seedhead formation and mildew incidence.

Comparisons of turfs grown under blue light versus gray light showed better turfgrass color and quality when grown under the blue light whereas fresh weight clipping removal and plant height were less. These differences were most evident at light intensities ranging from 25 to 45 per cent of full sunlight. In the case of bermudagrass, seedhead formation was reduced when grown under gray transmitted light compared to turfs grown in full sunlight. In contrast, seedhead formation was stimulated when grown under blue light as transmission values of more than 40 per cent of full sunlight.

Comparisons of light intensity affects showed that turfgrass shoot density was not influenced by the two types of light quality except at low light intensities. The minimum light intensity for acceptable growth and turfgrass quality of the two turfgrass species was 40 to 50 per cent transmittance of full sunlight when grown in blue transmitted sunlight and 60 to 70 per cent transmittance when grown in gray transmitted sunlight.

In summary, these data show that over-all turfgrass quality and performance are better when turfgrasses are grown in blue transmitted sunlight rather than in gray light, and that turfgrasses can tolerate a lower light intensity when grown in the blue transmitted light.

Comments: Light is one of the essential environmental factors required for the growth and development of turfgrasses. Light can be measured in terms of (a) intensity or quantity, (b) quality and (c) duration or day length. Both turfgrass quantity and quality are significantly altered under shaded environments. The decrease in light intensity under shaded environments results in a reduction in radiation energy available for the photosynthetic process. Due to a lack of carbohydrate synthesis, there is a general decline in turfgrass quality including a reduction in shoot density, rooting depth and rate of shoot growth. Associated with this is increased succulence, thinner cell (Continued on page 38)

Winter kill, fungus and disease can hit the best-kept fine turf areas. Excellent insurance to keep these areas in lush, living grass is a sod nursery for emergency repair. And the best way to perform the transplant operation is with a Ryan Sod Cutter. Ryan has a size and model to suit every need.

RyAN JR SOD CUTTERS (1)

... turf-world’s most popular sod cutters are compact and highly maneuverable. Self-propelled, easy-to-operate JR Sod Cutters are available in three models capable of cutting 9, 15, or 20 sq. yards of sod per minute. They’re ideal for average-size sod nurseries.

Attachment blades are available for all models for trenching, edging, tilling, pipe laying and sub-soil aerification.

Heavy Duty Sod Cutters (2)

... for large sod nurseries and big transplanting jobs. These extra rugged machines are built to commercial specifications. Five models are available, enabling you to cut up to three acres of sod per day. All models come in a choice of cutting widths from 12” to 24”. They operate smoothly and quietly with dependable, 2-speed transmissions. Write for FREE Ryan Equipment Catalog.

walls and a more delicate cell structure which is quite prone to disease invasion, traffic damage and heat, cold or drought injury. The above study shows that the minimum light intensity for adequate turfgrass quality and growth will vary depending on the quality of light transmitted and turfgrass species involved. The quality of light under a tree canopy is substantially altered. There is a general reduction in the blue and red wave lengths of the visible light spectrum and an increase in the percentage of green and far-red wave lengths. It is primarily the blue and red wave lengths which are absorbed by chlorophyll and utilized in the photosynthetic process. The importance of blue light is very well illustrated in this study. It is also the blue and red wave lengths which are "screened-out" by the tree foliage. This results in a predominance of green and far-red wave lengths under the tree canopy. Thus, the light quality under a tree canopy is reduced in those wave lengths which are most important for turfgrass growth.

Standard?. You Bet!

Porta-Span® bridges the roughest gaps with spans from 8 to 20 feet. And now, Standard offers three different styles: with matching wood railing, with chain railing, and without a railing.
Install Porta-Span® in about two hours. Set it practically anywhere — over streams, gulleys, marshy areas, or in parks — without need of footings or a base. Move it when you like, and even store it in the winter.
Porta-Span® carries up to 2500 pounds or 15 persons. It's available in widths of three or five feet — big enough for golf cart, snowmobile or pedestrian traffic. And, like most Standard products, Porta-Span® is practically maintenance-free. Write or call us today for more information on Porta-Span®.
