The formula sounds so easy: Provide grass with optimal moisture and it will thrive.

For golf courses, getting the water on the grass is the simple part, thanks to sophisticated irrigation systems that supplement unpredictable rainfall.

Getting the water off the grass - and out of a waterlogged soil profile - is a more formidable challenge.

One of the most common golf course turf problems is excess water trapped at the surface. When water is unable to permeate topsoil, the result is surface ponding and an unstable surface that inhibits turf growth and invites turf diseases and soil compaction. Poor drainage can cost a golf course in both obvious and hidden ways:

Reduced play days and cart rental income; damage and scarring to fairway turf; turf renovation and restoration; reduced resistance of turf to drought; turf die-back in winter, and less enjoyable playing experience for golfers.

Until recently, the only cure for poor drainage has been major reconstruction of fairways and greens using conventional drainage methods that involve trenching, re-establishment of turf and lengthy disruptions to play.

In the mid-1990s, Hartman Companies of Victoria, Minn., introduced to the United States a proven drainage technology from the United Kingdom called Slit Drainage. The new surface drainage system consists of an intensive grid of parallel slit-trench drains that removes excess surface water before it has a chance to pond and damage the soil surface. Slit drainage, according to Jeff Hartman, founder and president of Hartman Companies, is capable of draining an area three times faster than conventional drainage (i.e., farm-field style drainage) without an increase in cost.

(Continued on Page 5)
Here is how slit drainage works: Main and lateral pipe drains with a porous fill to the surface are installed parallel to the fairway. Then a perpendicular network of gravel-filled 1-inch wide by 10-inch deep slits, on 16-inch spacings, are installed laterally, creating an intensive drainage grid which can remove surface water rapidly.

After construction, new grass growth covers the slits in 10-14 days. The lateral trenches are topped with a sand mix and also recover quickly. Wider trenches are covered with a sand mix, and then covered with sod to provide a natural playing surface.

The specialized machines the company uses to create the lateral slits and fairway drains are manufactured in the U.K. and have been used successfully for many years on golf courses in Europe. Main and lateral trenches are excavated using a Shelton Super Trencher. The Super Trencher cuts a trench up to 5 inches wide and installs 2-inch or 4-inch tile. Excavated soil is conveyed into a wagon and hauled away to avoid leaving a mess.

In a separate operation, the trenches are backfilled with buckshot stone to within 3 inches of the surface, then topped with a sand mix. Then, the whole area is top-dressed with 40 tons per acre of sand, about an eighth of an inch thick, using a ty-crop spreader.

Slit drains are installed using a Shelton twin-leg gravel bander. Two hollow knives, at 16-inch centers, are mounted to the underside of a gravel hopper that is pulled by a tractor. Buckshot gravel is fed into the slits as it proceeds.

"By allowing the adjacent turf to root in the aggregate, without the addition of a finer top soil, maintains a high infiltration rate into the slit drain, which is required to remove excess water," explains Tom West, a Hartman Companies sports-turf contractor. "The excess surface water moves into the columns of coarse aggregate and is carried away by the lateral drain pipes to a collector drain pipe, which leads to an outlet ditch."

The primary idea of slit drainage, according to West, is to remove the excess surface water before it has a chance to pond, thereby softening the ground surface and promoting turf growth. The design for each slit-drainage or gravel-band system, he says, includes consideration of depth, soil texture, spacing and slope. Drain depths will vary depending on the topography of the area, since drains must remain on grade, according to West.

The art of slit drainage takes place in the planning stage, West says. "We have to pot-hole where drains cross irrigation lines to check depths and plan drains to go beneath or over the irrigation pipes. In order to protect the existing irrigation system, we need to constantly stop and start the trencher."
Water On, Water Off—
(Continued from Page 5)

This is one reason we don’t backfill as we trench."
Slit drainage has gained rapid popularity among area
golf courses because of the many advantages it offers over
conventional drainage alternatives. "The traditional
approach to drainage was to re-grade a fairway or green
and re-establish the area with new grass," West says. "This
traditional approach typically took that portion of the
course out of action for a whole year. Now, for the same
cost per square foot, we can provide more effective
drainage and the area can be used immediately."

Jeff Hartman points out that golf courses typically allo-
cate a certain portion of their annual maintenance budget
for drainage. In most situations, when a course has con-
tracted with Hartman to upgrade drainage on a fairway or
green, superintendents and general managers are eager to
bring other problem areas on the course up to the same
standard. "It becomes a revenue-based decision, once they
observe how minimally the upgrades disrupt play."

Golf courses often apply the savings they realize from slit
drainage to more drainage work or other course improve-
ments, Hartman says.

Hartman Companies’ primary clientele are private clubs
that cater to revenue-generating tournaments. The revenue
is dependent on keeping the course open and allowing
carts. Good drainage allows these clubs to make more
money. Members also value good drainage because the
course does not have to close down for so long after heavy
rains.

The proof and results of Hartman’s slit-drainage system
can be observed at Brackett’s Crossing, Interlachen, Golden
Valley, Midland Hills, Wayzata and a number of other
Minnesota golf and sports turf clubs.

And the results were on display for the world to see in
August 2002 when Hazeltine National Golf Club hosted the
PGA tournament. More than three inches of rain drenched
the course Friday night and Saturday morning, and only a
herculean effort by hundreds of maintenance workers
allowed the course to be playable on Saturday. The point,
however, is that the course was made playable despite the
rain, and earlier drainage projects by Hartman Companies
contributed to that favorable outcome.
