

2001-2002 Snow Mold (*Typhula ishikariensis* and *T. incarnata*)

The corporation-sponsored snow mold fungicide field study was conducted during the fall and winter of 2001-2002. Treatments were applied preventively on the Treetops/Sylvan Resort in Gaylord, MI on the dates indicated in Table 1. Treatments were applied to four replicate 6' x 9' creeping bentgrass (*Agrostis palustris*)/annual bluegrass (*Poa annua*) fairway plots where the turf was maintained at approximately ½" height of cut. Liquid treatments were applied with a CO₂ backpack sprayer at a pressure of 36 PSI and a volume of 100 GPA using a flat-fan, double-nozzle boom, unless otherwise indicated in Table 1. Granular products were pre-weighed and hand-applied.

Permanent snow covered the plots from late December through April 13. The study was rated on 16-April, 2002 immediately following snow-cover melt-off. The predominant snow mold species was *Typhula ishikariensis* with lesser amounts of *Typhula incarnata*. Microdochium patch (*Microdochium nivale*) was also observed and was the predominant snow mold on some plots as indicated in Table 1.

As can be seen in Table 1, disease pressure was only moderately severe at Tree Tops this year. Disease pressure was also somewhat uneven across the study, leading to variability in the data, except with the most efficacious treatments. As in recent years, tank mixes of standard fungicides of varying chemistries seemed to perform the best. Interestingly, 18 of the 19 best performing treatments all included chlorothalonil or PCNB.

Phytotoxicity and turf greening effects were observed in some plots, as indicated the data table.

Table 1. Michigan State University Snow Mold Data, 2001-2002

Location: Tree Tops/Sylvan Resort, Gaylord, MI

Rating Date: 16-April, 2002

Rating Scale: Percent plot area diseased with a combination of *Microdochium nivale*, *Typhula ishikariensis* and *T. incarnata* unless otherwise noted.
