The Proper Care of Greens requires 
The TORO Del Monte Greens Rake

For removing the grain from creeping bent or Bermuda grass putting greens . . . also for raking up the matted grass so the mower can cut it properly . . . the Del Monte Greens Rake is an exceedingly handy tool. Thirty inches wide . . . a large green can be covered quickly. Spring steel teeth, ½ inch apart. Pressure can be regulated by operator. Use it regularly to prevent graining and maintain a true putting surface.

FEEDGREEN
The Organic Fertilizer of Real Merit

Analysis 8-5-3

Feedgreen is gaining new friends every day.
Ask any Greenkeeper who has used it.

We claim for Feedgreen all the virtues of well turned barn yard manure concentrated ten times. We claim that it more nearly approaches the natural plant food for grass than any manufactured fertilizer on the market.

Its benefits are quickly apparent and long sustained. A trial will prove our contentions. Compare dollar for dollar value with other products.

PRICE—Per ton $70.00—100 lb. Trial Bag $4.00 Also Other Golf Course Fertilizers

THEY JUST DON'T MAKE 'EM
ANY LIGHTER RUNNING

NO part in the entire construction of
the Ideal Greensmower is of any-
thing but the finest materials—built on
the most approved design.

Pushing is practically effortless, because
the finest grade of ball bearings give
smooth action, and aluminum side
frames and roller give remarkable light-
ness.

To sharpen or service this perfectly built
mower is simple. The four-inch high-
speed reel has seven keen blades that
trim the greens to perfect smoothness.
But, you must try the New Ideal Greens-
mower to realize its superiority. Write
today for the interesting description.

IDEAL GREENSMOWER
Drainage
An Essential Element of Golf Course Maintenance
BY H. E. COTTON, Municipal Engineer

HOW early in the spring or how soon after a rain can play be resumed? Excessive moisture in the ground as a result of spring thaws or rains, generally leaves conditions underfoot unsatisfactory for some time after they become favorable overhead. To shorten this time interval is the aim of every golf club official and greenkeeper, for it affects finances—in two ways. It decreases income, especially on "daily fee" courses, delays maintenance and makes it more costly.

The problem of acquiring and maintaining a good playing surface at all times during the playing season and especially early in the spring or soon after heavy rains, generally involves either the removal of surface water or the removal of ground water or both. Local conditions will usually indicate the kind of drainage needed. Eroded surfaces or water standing in low places for long periods are conditions which indicate the need for surface water removal. Soggy or springy areas or water appearing on hillsides are evidences of the need of subdrainage. These places have the distinct habit of making themselves known. Tractor wheels or treads sink in and mar the turf, and mowing operations and playing are hindered for a long time after the remainder of the course has dried out.

Surface Drainage

RAINFALL which is not absorbed by the soil, will flow over surface slopes to a natural outlet if such slopes and outlet exist. Surface water that remains spread out is more likely to be absorbed than if it were concentrated. And there is less danger of gulleying when the water is not concentrated. A greenkeeper knows that a smooth surface will remain smooth, whereas a rough one will become more gulleyed.

When surface water is concentrated in a draw or a gulley, erosion may occur. A good stand of sod in the bottom of the draw is a possible remedy for erosion. However, when the grade of the draw is too steep to permit seed or sod to become established between rains, the removal of surface water in an underground pipe line is necessary. Catchbasins at frequent intervals prevent the accumulation of enough water to damage the draw. After such a pipe has been in operation long enough, the sod will become established firmly enough so that it will absorb more and more of the water passing over it, especially if the pipe...
acts also as a subdrain.

Water standing in low places may be removed by either catchbasins or subdrains. The latter is feasible only when the character of the soil is such that water will pass through it with the required rapidity.

After the water has reached a stream or open channel of some kind, it needs further attention. If the stream is of any consequence, it may require the removal of silt, gravel and debris at some points, and protection against erosion at the other points. Brush mats, posts backed up with branches, and rock rip-rap are three methods of protecting the banks. If the stream is not too large it may economically be enclosed, thereby practically eliminating maintenance work.

Wherever it is necessary to cross a ditch or an open stream, either with a driveway or a fairway, a culvert pipe or bridge will afford a dry crossing.

Subdrainage

If properly designed and constructed, subdrains are very effective in removing water from most soils. The layout of the drains and their depth and spacing must be governed by local conditions.

For nearly level ground, the mains and submains will follow the natural drainage traces while the laterals, except those which are placed for the purpose of intercepting seepage water, will branch out in the direction of greatest slope. The layout should be arranged so that the areas of double drainage are reduced, as far as possible, to a minimum.

The depth and spacing of the laterals (subdrains) should be such that the ground water level is lowered to a point that the top soil will become stable and yet sufficient moisture will be available for the growth of grass during the dry season. In other words, the course can be over-drained as well as under-drained.

During times of drought, plant roots receive their moisture from a source below the root zone. This moisture which rises in the soil is known as capillary moisture. In extreme cases, not often encountered, it may be possible to drop the ground water table below the reach of capillary action and thus endanger the health of the grass. Capillary action is illustrated by the drawing up of oil in a lamp wick or by the action of a liquid when the edge of a blotter is dipped into it. Table No. 1, from the Department of Soil Technology, Cornell University, shows how soil texture affects capillarity.

</tbody>
</table>

The quantity of water raised above the water table varies as to the character of the soil and as to the distance above that source, as indicated in Table 2. Capillary lift approaches zero in loose organic soils like peat, on account of the insulating action of large air spaces. Such soils are rather easily over-drained.

### TABLE 2

| Quantity of Capillary Water Raised per Day, Pounds per Square Foot of Soil |
|-----------------------------|-----------------------------|-----------------------------|
| Height above sources        | Soil                        | 1 ft. | 2 ft. | 3 ft. | 4 ft. |
|                             | Medium fine sand            | 2.37  | 2.07  | 1.23  | 0.91  |
|                             | Medium clay loam            | 2.05  | 1.62  | 1.00  | 0.90  |

Due to the varied conditions which may exist relative to the water table, the amount and extent of capillary rise and the permeability factor of the soil, all of which may vary for each soil class, it is impossible to outline a rule of thumb method for depth and spacing of subdrains. It is advisable to employ the services of a competent drainage engineer who has had experience with golf course drainage.

### Depth of Subdrains

For golf course drainage, engineers are generally recommending a depth varying from 2 to 4 feet. The depth of the drain refers always to the distance the bottom of the trench is below the surface of the ground. For dense clay soils a depth of 2 to 2½ is commonly used. For the medium soils such as a sandy clay loam, a depth of 2½ to 3 feet is considered advisable. For the more open soils such as the sandy loam soils, the depth should be 3 to 4 feet.

---

No matter how well the soil has been prepared, or how fully the thousand and one little details have been taken care of—if the seeds you plant are not right, it is largely wasted effort. This is why we emphasize, at all times, what we term "The Henderson Standard of Quality," rather than our prices.

We have always believed that there is a demand for the highest grade of Grass Seed—Grass Seed that could be depended upon, and the results have fully justified this belief.

Let us quote you on your requirements, and you will be surprised to find that the prices for Seeds of the Henderson Quality are about the same as you have been paying, but with a vast difference as to results.

We can help you with your course problems. Our staff of trained men is competent to assist you, whether it be a complete new course, the renovation of your present one, or the usual problems that come from day to day.

An inquiry does not obligate you in any way.

PETER HENDERSON & CO.

SEEDSMEN

Everything for the Golf Course

35 Cortlandt St. New York City
Drains should not be placed below the surface of a layer of hard pan or other impervious material unless their trenches be backfilled with some pervious material, such as crushed rock, cinders or gravel, up to the top of the impervious layer.

Spacing of Subdrains

C. G. Elliott, in "Engineering for Land Drainage," gives the following recommendations for spacing of subdrains:

"In close, dense soils, largely clay, 30 to 40 feet; coastal plain lands composed of mixed clays with fine sand and uniform structure, 60 feet; alluvial gumbo or heavy soils but with granular structures, 70 to 80 feet; alluvial, glacial drift and sandy loam soils, with clay subsoils. 100 feet; sandy lands and soils containing considerable quantities of vegetable matter and those without subsoils having a liberal supply of sandy or gravelly material, 150 to 200 feet."

Seepage Water on Hillsides

To eliminate soft spots appearing on hillsides caused by seepage water, the subdrains should be placed in a direction as nearly perpendicular as possible to the underground flow. Their trenches should be backfilled with gravel or crushed rock up to within about 6 inches of the surface. Their depth should be such that the seepage flow will be intercepted but usually need not be more than 4 feet.

Economies

Naturally the question is, can subdrainage be afforded; will it be economical? For a subdrain to answer the question of economy affirmatively it must meet the following requirements: strength, durability, and continuous drainage efficiency. A drain pipe must be strong, otherwise the weight of mowing and other maintenance machinery will crush the pipe where it is necessary to lay it close to the surface. Immunity to the damaging action of frost is also necessary for shallow installations.

Durability is essential along with strength if the pipe is to have a long life, and consequently a low yearly cost of service. Replacement and repairs should be kept down to a minimum. Of equal importance with the above two requirements is continuous drainage efficiency. A pipe which is easily crushed, which separates at the joints and admits soil or gets out of alignment, will decrease in drainage efficiency until after a few years it becomes entirely clogged up and useless. The selection of a drain meeting the above requirements, will insure in the long run economical drainage that will pay dividends in increased playing hours and less maintenance expense.

Flood Prevention

Flood prevention on low areas is a special drainage problem sometimes encountered on low land which is subject to flood water flowing across or backing up on it. Such land can often be made an asset instead of a liability. By building an earth levee, the flood water may be kept off. A simple yet efficient means of providing natural drainage for surface water that collects back of the levee is to pierce the levee by means of a drainpipe and attach an automatic drainage gate to the stream end. Such gates prevent any backflow of flood waters. When the water behind the levee is the least bit higher than on the stream side it flows out automatically or naturally.
Keep the scars of BROWN PATCH off your greens...

Leading greenkeepers use this effective method

In the next few weeks the strongest and healthiest turf may be scarred—perhaps completely ruined—if it is unprotected against brown patch. The disease has no respect for the cost of your greens!

But damage by both large and small brown patch can be prevented. Greenkeepers of hundreds of leading golf clubs know this by their years of experience. They apply Semesan or Nu-Green regularly, and their turf stays green and velvet-smooth. Or, if the disease has already developed, a prompt application soon restores the grass to normal health.

For the control of brown patch, 1 pound of Semesan or Nu-Green to 50 gallons of water will treat 1000 square feet of turf by sprinkling. Applied with a power sprayer, 50 gallons of Semesan solution will treat 2000 to 3000 square feet—50 gallons of the Nu-Green solution, 1500 to 2000 square feet.

Damage from snow mold, which attacks the greens in early spring, may be prevented by applying Semesan just before the ground freezes. Use 50 gallons of the solution to each 1000 square feet of turf.

SEMESAN is advised when soil fertility is high, but controls brown patch under all conditions.

- 5 lbs. ............ $13.00
- 25 lbs. ............ 56.25
- 100 lbs. .......... $220.00
- 300 lbs. .......... 645.00

NU-GREEN contains the same effective ingredient as Semesan. Recommended where fertility is lower.

- 5 lbs. ............ $ 9.00
- 25 lbs. ............ 37.50
- 100 lbs. .......... $145.00
- 300 lbs. .......... 420.00

Preparing Compost Topdressing

BY ERNEST B. LORD, Greenkeeper

At this time scarcely two greenkeepers prepare compost in the same way. Here at Cohasse we are very fortunate in having plenty of good fertile land adjoining the club grounds, this having previously been a farm. Therefore we can readily and economically avail ourselves of sufficient topsoil with which to build up our compost piles.

The base of the pile is a thick layer of topsoil, which is then covered by manure, then more topsoil, and so on, until the pile has been built the desired size. One part manure is used with two parts topsoil. This pile is turned with forks once or twice a year to mix it well together, we using an older supply which we keep on hand.

We have a large barn nearby in which we keep several yards of dry compost, and here also we have a Royer compost machine. and on rainy days, or during other broken time, we run this material through that it may be ready when needed. The Royer machine was not designed to screen compost but to pulverize it and separate the large or medium sized stones from the finer material, but by placing a large screen of five-eighths mesh about five feet from the front of the machine, we get very satisfactory results, as nearly all stones large enough to be objectionable rebound off the screen and are thus prevented from becoming mixed through the topdressing.

Certainly, a few stones up to the size of a white bean go through the screen, but I have found it best to sweep the greens after each application of compost no matter what type of screen is used. For power we have a one and a half horse power electric motor attached to the scaffolding above.

Two men work this machine to the best advantage; one to pass the compost to within a few feet of the machine, while the other shovels it into the hopper. In this manner we can prepare three yards of material per hour, which seems to be a very great saving over the old methods of screening. Also the compost prepared in this way is so much finer and can therefore be spread more easily.

I am well aware that few greenkeepers have such a valuable supply of topsoil available and in many instances are handicapped by lack of shed room for storage, etc. which so simplifies the problem of preparing compost.

New Golf Course at Del Monte

Another new golf course is to be laid out on Monterey Peninsula. This important information was made public for the first time when S. F. B. Morse, President of Del Monte Properties Company announced a $1,000,000 budget for new improvements in the Del Monte area. The new links is to be laid out adjacent to the steeplechase course East of the present Del Monte polo plant.

Construction of the steeplechase course will be initiated this summer. However, Morse states that the golf course is to be built at a later date when required. The object in laying it out now is to plan it so that it will border and overlook the steeplechase course without interfering with the latter in any way.

September, 1930
