**USDA-ARS** Rutgers University Michigan State University

## **Objectives:**

1. To develop elite clones of creeping bentgrass with multiple pest resistances and stress tolerances that can be delivered to the seed industry for use in synthesizing new creeping bentgrass cultivars broadly adpated to a range of ecological and environmental conditions including reduced pesticide application.

Start Date: 2003

Project Duration: three years **Total Funding**: \$170,817

(three institutions)

Crosses have been made between creeping bentgrass and creeping x colonial bentgrass hybrid plants selected during Phase I of this project, creating new progeny populations. Progeny populations will be screened for resistance to dollar spot and snow mold pathogens and will also be evaluated for DNA markers previously associated with resistance to these two diseases. Plants will be selected based on both DNA markers and disease evaluations to test the effectiveness of DNA markers as a selection tool. Selected plants will be crossed with additional elite plants to create additional disease-resistant populations.

This research will build upon previous results of Phase I of this project and will tie into previous results that have mapped putative genes for disease resistance in creeping bentgrass. Elite clones of creeping bentgrass and creeping x colonial hybrids will be released to private breeders for use in developing new varieties for the golf industry.

A creeping bentgrass nursery demonstrating genetic variation for dollar spot resistance, Amherst, Massachusetts.

Activities for 2009 focused on field evaluations of dollar spot and snow mold on progeny from elite crosses, extraction of DNA from leaves, and the initial assay of DNA markers. Replicated field evaluations were established in Massachusetts, New Jersey, and Maryland in 2007 and 2008 and evaluated in 2009.

In 2010, data will be collected on disease resistances of field-grown plants and DNA markers. Selected plants will be used to create new hybrid plants, progeny populations, and releases of individual clones or genotypes to bentgrass breeders who are developing new varieties.

## **Summary Points**

- Creeping bentgrass plants with improved resistance to both dollar spot and snow mold fungi have been identified and propagated.
- These plants will be released to private turf breeders for use in developing new and more disease-resistant creeping bentgrass varieties.
- This research has contributed to the identification of specific genes for resistance to snow mold and dollar spot diseases, which can be used to design more efficient and effective breeding methods based on using DNA marker technologies. These methods will be tested in the current phase of this project.

Two creeping bentgrass clones demonstrating resistance and susceptibility to the dollar spot fungus, Sclerotinia homeocarpa. These two clones were used as parents in crosses to identify genes for resistance to dollar spot
