Prostrate spurge (6) is an annual which reproduces by seed only. It is sometimes called milk purslane and spotted spurge. Common throughout the eastern and middle western states, it is found less frequently along the Pacific Coast.

Growth of prostrate spurge in lawns, gardens, fields, and waste places causes the plant to form dense mats of branches radiating from the central taproot. One plant can cover a square foot.

Stems are succulent, slightly reddish, and somewhat hairy. Stems have a milky sap. This sap causes a rash reaction if brought in contact with skin of sensitive persons.

Leaves are opposite on the stem, simple, and oblique (each leaf margin is not the same length). There is usually a reddish-brown spot on the leaf surface.

Small inconspicuous flowers (7) borne in the leaf axils produce many tiny black seeds (8).

The root is a taproot and can be pulled up easily when the soil is wet.

Prostrate spurge will grow well under trampling where foot traffic has destroyed other grasses. As long as there is healthy vigorous turf, prostrate spurge will not have a chance to invade.

Disodium monomethyl arsonate (DMA) and silvex applied to turf 2 to 3 times when spurge is actively growing will control it.
