Red Alert for Spraymen
(from page 9)

less calcium, or other elements in water samples.

The question among spraymen who deal with aquatic weed control is how to apply findings such as these. The answers, once water samples are analyzed are simple. For example, Dr. Toth reports that rainbow trout and other fish suffer from nickel and other heavy metals. Rainbow trout do not survive in water with more than 0.1 ppm of nickel. But at the same time, brook and brown trout can survive in water at this level of nickel content.

Dr. Toth reports that, based on atomic absorption analysis of water, his research group can accurately predict what water can be stocked with certain fish in order to assure maximum productivity and eliminate fish kill. For the spraymen who treats water for weed control before a restocking program, such information based on water analysis may prevent many later problems.

Sterile Lakes Are Problem

Further, Dr. Toth says, the damming of a stream to form a lake without checking the tributary water may lead to creation of a sterile impoundment. This is illustrated in the case of Matawan Lake at Matawan, N. J. Two tributaries to this lake contributed sufficient sulphuric acid and soluble aluminum to kill almost all of the animal and plant life. The pH of this lake has been as low as 2.8 with soluble aluminum content exceeding 25 to 30 ppm and with an iron content of 12 to 25 ppm. It is obvious that water of this type is unsuitable for recreational or industrial use.

Attempts to modify the composition of stream waters in this area using limestone or basic slag beds have not been successful.

Establishment of farm ponds in the New Jersey coastal plains area of the Southern region also creates problems when these ponds are used for recreation. The low content of bases and other nutrients in water of this region requires that the waters be periodically limed and fertilized for fish production. Large natural or impounded lakes and ponds in this region cannot be treated economically in this manner and must be considered as having very low fish productivity ratings.

Establishment of farm ponds in the New Jersey inner coastal plains area often leads to conditions similar to that in Matawan Lake. Use of water from such ponds for irrigation of lettuce, tomatoes, and peppers can lead to severe crop damage. Waters of this type, however, can be treated with superphosphate and lime to raise the pH and precipitate the heavy metals.

Dr. Toth reports that his group can analyze with atomic absorption and accurately predict what water can be used effectively for irrigation of crops and golf greens. Burning of golf greens after irrigation has been common in the past. Recently, Dr. Toth reports, he analyzed irrigation water used on a golf course which was suffering burned greens. Water being used was high in copper and acid, thus causing the burning. Analysis of the water before irrigation could have prevented this situation and others like it.

Establishment of farm ponds in the New Jersey coastal plains area of the Southern region also creates problems when these ponds are used for recreation.
