Industry's Stake In Helicopter Spraying

Weed control by the helicopter sprayman is becoming a vital segment of the industry. This relatively new method of applying herbicides is on the upswing for a number of practical reasons, a major one being the efficiency with which application of chemicals can be made in hard-to-reach areas.

Equipment is being designed especially for the use of this aerial mobile platform, chemicals and drift control agents are formulated especially for its use, and pilots are getting the training and experience needed to make best use of the package.

Putting all the needed pluses together becomes a technical operation, one in which many in the chemical weed control industry have a big stake. Those with a big responsibility in this respect include the customers who hire custom helicopter applicators, chemical suppliers, equipment manufacturers, pilots, insurance carriers and others— including the citizenry in general. The image of pesticide use hinges to a great degree on how well aerially applied chemicals can be handled, a facet of the business which good helicopter operators keep in mind at all times.

Typical of such pilots who have pioneered helicopter herbicide application is owner-operator William J. Perdue, vice-president, Alco Helicopters, Inc., at Lake Wales, Fla. A navy man during World War II, Perdue joined the army reserves after the war, became an army aviator, and later flew helicopters for the army. He was the first helicopter pilot employed in Florida by a citrus cooperative for the sole purpose of spraying citrus crops. This was in 1961 and at that time the only ship so employed. Today, almost 20 helicopters are owned and operated by...
citrus companies for this type spraying.

Since, Perdue has piloted helicopters for spraying power line rights-of-way, and purchased his own ships and operated his own business, both individually and as a partner. He has broad experience in using herbicides for weed control, particularly on aquatics.

**Busy Equipment**

Alco, Inc., besides Perdue, consists of Consolidated Financial Corporation and Alico Land Development Co. This group owns and operates 3 ships under the management of Perdue. They keep equipment busy by diversifying their spray operations to include citrus, farm land, rights-of-way, pasture, canal, and drainage spraying. This continuous operation, of course, is a prime factor in an efficient helicopter operation.

Perdue's experience as pilot and businessman leads him to point up the industry's need for a responsible spray program. A helicopter with spray equipment plus chemicals, and a pilot who can fly it do not always guarantee weed control. Pilots need training and owners need experience. Customers who hire them need to know that they are capable of doing a responsible job. Liability cases settled both in and out of court prove Perdue's point.

Depending on the damage caused by spraying and the circumstances surrounding a particular case, liability can reach almost any person or company even remotely akin to the operation. Among those who might prove to be accountable are the makers of the spray and/or equipment, formulator of the chemical, owner of the ship, pilot, and finally, the customer who hires the work done.

The customer may be held accountable for resulting damage,

Alco helicopter pilot Pat Gray.
for any number of reasons. Among customer responsibilities are care in determining the qualification of the custom sprayman. In many states, the customer or land owner cannot delegate responsibility to others for any damage which may result from use of chemicals. Because careless aerial spraying can result in drift problems (2,4-D drift lawsuits have been instigated on damage more than a dozen miles from the spraying site), it is mandatory that customers check references before hiring a custom applicator. Perdue's original statement is: "Know your pilot. Know his boss."

**Experience Needed**

Factors besides experience also account for troublesome spray problems. Because of lack of experience, or lack of judgement, applicators will spray during windy conditions. They may take a chance because they have bid a job too low. In any case, they find themselves in trouble and a liability problem to face.

Perdue points out that experienced spray pilots are in short supply. The future appears brighter because of the many capable pilots being trained by the armed services. However, these pilots, though adept at handling the ship, need comprehensive training in spray techniques and in handling of chemicals. In the opinion of Perdue, too few operators give pilots enough thorough training.

As an example of pilot training needed, so that the new pilot can do a successful job and not jeopardize the industry image, Perdue speaks of the need to avoid the vortex. The aerodynamic characteristics of the helicopter's rotor system creates "blade tip vortices." These small tornado-shaped wind tunnels trail aft of the ship's main rotor blade tips. As the forward speed of the helicopter increases, the vortices tend to become more horizontal. When speed is reduced they move to the vertical. In any event, they create an undesirable area in which to introduce the herbicide spray. Many operators use the vortices to an advantage to increase swath width when applying insecticides. But herbicides cannot be applied by this method.

Another point is based on the helicopter's ability to reverse its direction. It can make a spray turn in as little as 5 seconds. But if this is done there is the possibility that small particles of spray still suspended from the initial spray run will be kicked by the blast of the main rotors. This leads to complicated drift problems. Here again, Perdue stresses pilot experience and the need to: "Know your pilot. Know his boss."

**Inversion**

Inversion is another weather condition which exists only locally as a rule. It is seldom noticeable except to a pilot. An inversion, Perdue points out, takes place when the cool evening air spills into low lying areas and causes the warm moist air to be displaced above it. In an inversion, particles of spray are caught up in the warm moist air to be displaced above it (20 to 30 feet above the ground) and can be carried several miles before release. Again, the experienced pilot will recognize the inversion and cease spraying until normal weather prevails.

Safety in application is mandatory as is safety in operation of the helicopter itself. Perdue believes careful maintenance can reduce the hazard in aerial spray work. He states that operational costs are unusually high in Florida because of sand particles. Helicopters in operation for Alco, Inc., are cleaned daily. Epoxy paint is used at intervals, and both ship and accessory equipment are sprayed daily.
with a formulation of diesel oil and oil.

Perdue believes and practices careful business management. He will not spray nor permit his pilots to operate if there is even a slight chance of drift because of unsatisfactory weather conditions. He frankly admits that success of his and similar operations is based on repeat business. Thus, every job is carefully bid and spraying done as conditions permit. He prefers to bid by job rather than by hour. When handling a job by the hour, there may be pressure from the customer to push the operation when weather is questionable.

**Clock Recorder Used**

Perdue uses Bell 47 G-5 ships and has for a number of years. He keeps accurate records of running time by using a 36-hour Servis clock recorder. This clock logs loads and time for each load. The clock is also very valuable in providing a check of ground time for loading. Anytime this is excessive, a check of loading procedures is in order. No ship is operated with more than 800 hours on the engine, and engines are usually changed at 600 hours. Again, Perdue points out that this is a practical safety factor.

Growth of helicopter spraying for both crop and non-crop weed control, particularly aquatics, has been great during the past decade. Perdue expects the method to grow even more for several reasons. Helicopters can work in more congested areas than can fixed wing aircraft. They can land closer to the spraying site in congested areas where air strips for fixed wing aircraft are not available, thus reducing ferrying time. Also, the helicopter is excellent for precision application and for inspection and survey work prior to spraying. Costs are comparable to other types of spraying when all factors are considered.

With leading manufacturers and formulators of chemicals providing new thickeners and invert emulsions, and more precise spray nozzles and booms, Perdue sees only growth for this phase of the industry. He stresses, however, that responsibility by everyone concerned with this type spray program will continue to be needed to assure growth.
