The dandelion is a winter broadleaf weed which can be treated with 2,4-D.

AFTER THE FACT

If your pre-emergence weed control didn’t work, here’s a guide to the post-emergence choices.

WARM-SEASON

by Euel Coats,
Mississippi State University

Post-emergence herbicides are applied after weeds have emerged. Post-emergence herbicides act either by contact or after absorption and translocation (systemic).

Contact herbicides act rapidly, while translocated herbicides usually require several days for their phytotoxic action to be observed. Translocated types usually kill the entire plant, whereas contact herbicides kill only the contacted part of the foliage.

Best results will usually be obtained with post-emergence herbicides if plants are young and actively growing, and the air temperature is above 70 degrees Fahrenheit. Foliar applied herbicides are less effective if the soil is dry.

Consult the herbicide label for the optimum growth stage and environmental conditions needed to obtain the best results with a given herbicide. Surfactants are frequently recommended for use with post-emergence herbicides. For consistent results, use non-ionic agricultural surfactants sold specifically for use with herbicides.

Warm-season turfgrasses vary in their susceptibility to post-emergence herbicides. However, it is possible in most cases to discuss bermudagrasses and zoysiagrasses as a group and centipedegrass and St. Augustinegrass as a second group similarly in herbicide tolerance.

Many herbicides that can be used on bermudagrasses and zoysiagrasses cannot be used on either centipedegrass or St. Augustinegrass. Weed problems in warm season turfgrasses occur both in the growing and dormant seasons.

Winter grass weeds

Annual bluegrass is by far the most severe grassy weed infesting southern turf areas during the late warm growing season, through the dormant period, and into the early part of the next growing season. This weed occurs in all turf environments, especially in moist soils. Aside from decreasing the aesthetic value of turf, the primary objection of annual bluegrass in southern turf is the onset of other weed problems associated with the rapid die-back of annual bluegrass in late spring.

Bermudagrass coverage of bare spots is usually slow following fade-out of annual bluegrass, leaving sections of the soil surface exposed. Weeds tend to germinate in bare areas.

A particular problem is goosegrass, which is usually difficult and expensive to control.

Pronamide application made as early as November or as late as April will give annual bluegrass control in dormant turfs. Ideally, treatment should be made prior to seed production to reduce next year’s seed source. Application prior to seed production is also early enough for effective annual bluegrass control while not interfering with the transition of bermudagrass. The earlier a dense bermudagrass canopy develops, the more competitive the turf will be with summer weeds.

Another approach employed on many golf courses is to use a post-emergence application of a non-selective herbicide such as paraquat or cacodylic acid prior to the breaking of bermudagrass dormancy. This usually does an excellent job on annual
bluegrass, as well as any annual broadleaf weeds present.

However, injury is often encountered if application is delayed until the bermudagrass begins breaking dormancy. The degree of injury is dependent on the amount of green foliage present at the time of application.

**Winter broadleaf weeds**

Important broadleaf weed species include: common chickweed, henbit, clovers, mouseear chickweed, lawn burweed (spurweed), dandelion, wild onion, wild garlic, plantains, speedwells and others. Henbit, chickweed and clovers dictate that something other than 2,4-D be used for post-emergence broadleaf weed control.

In dormant bermudagrass and zoysiagrass, Banvel or a two- or three-way herbicide combination containing Banvel are usually used. The phenoxy herbicides are safe on completely dormant turfs. Actively growing turfs vary considerably in their tolerance to phenoxytype materials.

St. Augustinegrass will usually tolerate 0.5 lb/A of 2,4-D with only minimal injury if the air temperature is below 80 degrees Fahrenheit. This may not seem important when using phenoxy on dormant, warm-season turfs, but invariably application is made at various stages during spring transition.

Turfgrasses are more susceptible to phenoxy injury during this transition period.

The combination of mecoprop plus chlorfluorenol is often used by homeowners, especially in St. Augustinegrass lawns. Wild garlic is a major perennial weed problem in many warm season turfs during the cool growing season.

A fall application followed by a spring application of 2,4-D for three or more years has been used for wild garlic control with varying degrees of success. Image, a herbicide recently labeled (1987) for use in turf has shown potential for more effective control of wild garlic than 2,4-D, and should contribute significantly to more effective management of wild garlic.

**Summer grass and sedge weeds**

Crabgrass and dallisgrass invade more turf acreage in the southern United States than any other grass. Post-emergence control of these two weeds, especially crabgrass, can be accomplished in centipedegrass with Poast.

In St. Augustinegrass, an application of Asulox will give reasonably good control of crabgrass and certain other annual grassy weeds. In bermudagrass and zoysiagrass, control can be achieved with MSMA, DSMA or CMA. In fact, dallisgrass control in bermudagrass and zoysiagrass relies heavily on these herbicides.

MSMA plus metribuzin plus surfactant gives good post-emergence control of goosegrass. Two applications of MSMA (2 lbs/A) plus metribuzin (½ lb/A) plus 1 quart of non-ionic surfactant per 100 gallon tank mix applied seven days apart will generally give excellent control of even mature goosegrass.

Remember, the methane arsonates can be used only on bermudagrass and zoysiagrass. Other grass weed problems in southern turfs include sandbur, bahiagrass, crowfootgrass and torpedograss.

Sandbur and bahiagrass can be controlled with methane arsonates, although several applications may be required.

No means of selective control of torpedograss in any southern turf species has been developed.

Both annual and perennial sedges are problems in the southern United States. Purple nutsedge and, to a lesser extent, yellow nutsedge, are the most severe problems. Yellow nutsedge can be controlled with Basagran. Roundup will control nutsedge when used as a site preparation aid.

Image, in addition to controlling wild garlic, will also control purple and yellow nutsedge, as well as many annual sedges.

Although broadleaf weeds are a problem throughout the southern United States in turf, no species appears to reach the level of infestation equivalent to that of the summer grasses.

Among the more important summer broadleaf weeds are prostrate spurge, prostrate knotweed, yellow woodsorrel, Virginia buttonweed and Florida betony.

**Summer broadleaf weeds**

As a group, they are rather difficult to control. Multiple applications of a two- or three-way hormone mixture are necessary for effective control and repeat treatments are often needed.

From our limited experience with some members of the group, we generally observe that the use of a good agricultural grade surfactant is warranted when applying a hormone herbicide.

A mixture of 2,4-D plus dichlorprop has given equal or better post-emergence control of Virginia buttonweed than other hormone herbicide mixtures in our research trials in 1984, 1985 and 1986.

We have observed that the level of Virginia buttonweed control can be increased an additional 15 to 20 percent if a pre-emergence herbicide, such as oxadiazon or Princep, is applied at the same time a post-emergence application is made. The increase attributable to the pre-emergence herbicide appears to be due to reduced regrowth or reinestation of Virginia buttonweed from seed.

**Cool season turfgrass weeds**

Weed control technology for cool season turfgrass overseeded into warm season turfs (bermudagrass) is somewhat limited. The small acreage has not justified the expenditure of re-
Common chickweed tolerant to 2,4-D, necessitates the use of other materials.

annual bluegrass control.

Broadleaf weed problems in overseeded turf are quite variable. A number of the common winter annual broadleaf weeds found throughout the southern United States during the dormant season may or may not be a problem in overseeded turf. Henbit, common chickweed, clovers, spurweed and mustards are among the more important of this group. Competition from the overseeded turf would seem to hold infestations down significantly. When a herbicide is needed, henbit, common chickweed and (or) clovers usually dictate the herbicide(s) that will be used.

These weeds are fairly tolerant to 2,4-D, necessitating the use of other “phenoxy type” materials. In general, Banvel or a phenoxy-Banvel mixture are recommended for broadleaf control where these weeds are present. Banvel or Banvel mixtures appear to be the most widely used for control of these weeds. Numerous two-way mixtures of Banvel and 2,4-D formulations exist on the market. These and the three-way mixtures Trex-San or Trimec are probably used more than Banvel alone. Weed-B-Gon for Southern Grasses, which is a mixture of mecoprop and chlorflurenol, is also used to some extent by homeowners. In overseeded greens where lawn burweed (spurweed) is the problem, Buctril or Brominal is a very effective and safe herbicide to use.
