PEOPLE ARE OFTEN A TREE'S WORST ENEMY

More urban trees are being killed today by the activities of people than are lost due to all the diseases and insects problems combined.

by Terry A. Tattar, Ph.D, Shade Tree Laboratory, University of Massachusetts, Amherst

Trees along our streets, in our parks and near our homes improve the quality of life in our cities and towns. And though all trees are threatened with pathogens, insects and stresses from the extremes of the environment, these urban trees face a much more formidable enemy, abuse by people.

It is ironic that urban trees provide so much enjoyment for people who in turn are often responsible for acts that result in tree death. The activities of people that stress, injure and often kill trees are known collectively as "people-pressure diseases," or PPDs.

The urban environment however, is not the only area where PPDs are found. Greater demands on campgrounds and forest recreation areas has resulted in PPDs being found there as well.

The most common forms of PPDs are caused by construction, soil abuse, lawn and garden equipment and improper tree care.

Recognition of the most frequent examples of PPDs will enable us to become aware of the PPD problem and be more effective in its control.

Building and road construction are by far the most frequent causes of injury to trees by people. Trees are injured by earth-moving equipment and by changes in ground level.

To protect these trees, barriers must be erected to protect the root system from being disturbed by construction.

In the past, efforts to protect the trunk from injury were mistakenly thought to be adequate to preserve trees. Small wooden "cages" were erected by contractors around large shade trees. The efforts failed because trees' roots extend far beyond the edge of the branches. These trees often died from extensive root injury and soil disturbance after construction was completed. It is important to remember that the roots of a tree extend far beyond the drip line. Roots can often be found at a distance from the trunk that exceeds twice the height of the tree.

Efforts must be made to protect as much of the soil area as possible from any disturbance by construction equipment. Identify trees scheduled to be preserved on construction sites before construction begins and then protect them from root injury and ground level change until all construction is completed.

Supports should not be left on the tree for more than one growing season.

Trenching, surface grading and storage of construction fill can all result in tree death.

The loss of either large or small roots places the tree in a state of imbalance and stress. The affected tree slows its growth and often begins to "die-back" in the branches of the crown. The tree in this state is often susceptible to attack by weak pathogens and secondary insects that wouldn't have been able to attack it when it was healthy and vigorous.

Loss of large supporting roots can also make a tree a potential hazard from falling. Root-injured trees should be examined by a professional arborist and removed if hazardous.

Construction-damaged trees often decline progressively in the years after construction, leaving property owners confused as to the cause of the tree's poor health. Ground-level changes can cause cut roots if the level is lowered or smothering from fill if it is raised.

The addition of asphalt, concrete, or more than a few inches of soil will change the amount of water and oxygen available to the roots below. If gas exchange is inhibited between the air and the roots, smothering and root injury can occur. Carbon dioxide from root respiration builds up, oxygen decreases, and eventually the roots die of suffocation.

Fill-damaged trees, like root-injured trees, grow more slowly and often die back in the crown within a few years after construction is completed. Secondary pathogens and insects are also a threat as decline progresses.

Too little, too late
It is possible to regain balance in some root injured trees by crown reduction pruning in the early stages of decline. It is also possible to remove fill from
over the roots soon after it has been added to prevent suffocation. However, these efforts usually come too late, and the total amount of injury sustained during construction is often fatal to the trees.

It is recommended, therefore, that tree protection, through the use of barriers to all construction activities around trees, be the main strategy to prevent construction damage to trees.

Tree wells with an aeration system over the roots can be helpful in saving them where a raise of grade is necessary. Too often the well is simply constructed around the trunk and most of the root system is covered with suffocating fill, often several feet thick. An aeration system is the key to preserving trees where the grade is raised (see related story). A properly constructed tree well can allow sufficient air to reach the roots to permit the tree to live and grow normally after construction. Many trees in such wells have been growing for more than 40 years.

Proper soil conditions are critical to the health of all trees. Chemical and physical changes in soils as a result of peoples' activities are termed "soil abuse."

Chemical injury from deicing salts, herbicides and improper use of agricultural chemicals are common forms of soil abuse.

Deicing salts, now in use on highways and walks in many parts of the country, contain sodium and/or calcium chloride, both of which are toxic to trees.

Small trees and shrubs that are exposed to salt-laden spray from traffic should be screened with burlap or other appropriate materials. Also, channel salt in water runoff away from the roots of trees and use salt-tolerant species in areas where exposure to salt is unavoidable.

Pesticides and fertilizers can be beneficial or injurious to trees, depending on if they are used properly or improperly. A common misconception is "If a little is good, a lot more will be better." Proper use of these chemicals includes strictly following label recommendations.

Weed-and-feed mixtures, in which herbicides are mixed with turf fertilizers, should be avoided around trees since the herbicide may be absorbed by the tree's roots in toxic amounts.

All herbicides should be considered potentially injurious to trees.

If a spillover occurs, identify the herbicide and try to pick as much of it up as possible. This may mean the removal of contaminated soil or detoxification of the soil using activated charcoal.

It is best not to water the herbicide-injured tree until as much herbicide as possible is removed. Even then, water only after the exact nature of the herbicide is known.

Some industrial strength non-specific herbicides are extremely toxic to trees and are quite persistent. Watering in these cases could spread the still-active herbicide, increasing the injury and possibly endangering nearby trees as well.

Carelessly used lawn mowers, string trimmers, snowplows, rototillers and other mechanized lawn and garden equipment are often involved when serious tree root and trunk injuries occur. Lawn and garden crews and homeowners need
to learn how to avoid injuring trees when using this equipment.

By removing sod near trunks and exposed tree roots, the need to mow or trim near trees is eliminated. Adding organic or inorganic mulches around the trunk and buttress roots will inhibit weeds, improve soil moisture retention and remove the need to drive equipment near the trunk and over exposed roots. Bright-colored guideposts along driveways will help keep snowplows and motorists on course and away from trees and shrubs.

Rototilling should not be allowed near trees because many tree roots, which grow in the top few inches of soil, will be cut.

If plantings are desired under trees, select only perennials and place them in a mulched area around the tree. Annuals that require yearly soil disturbance around the tree should be sited as far as possible away.

**Improper tree care**

Trees greatly benefit from proper care but can be severely damaged or killed by well-meaning but misdirected attention. Improper pruning and wound treatment, guy wire injury, petroleum jelly injury and suffocation from plastic wrap are some common examples of improper tree care.

Proper pruning helps trees by removing diseased, dying, dead and defective branches. A proper pruning cut is made by severing a branch as close as possible to the outside of the branch bark ridge.

### Salt-tolerant and salt-intolerant shade trees

The "wooden cage" fails because it doesn't adequately protect tree roots.

Avoid injuring or removing the branch collar during the pruning cut. Trunk and root wounds should be trimmed of loose, ripped and torn bark. Any wood splinters must also be trimmed and smoothed to facilitate wound closure. The wound should be shaped to remove minimal live bark and also to avoid creating pointed edges.

It is, therefore, not necessary to achieve an oval shaped wound. A thin coat of tree paint may be applied over the surface of a pruning cut or wound surface for cosmetic purposes. Guy wires, cords to secure wraps or anything restricting the growth of the tree will eventually strangle it if they are not removed. Many valuable shade trees are killed each year because those who planted trees neglected to return and remove guy wires when they were no longer needed.

Trunk supports should not be left on the tree for more than one growing season. Hemp cords used to secure trunk wrap or planting ball wrap do not biodegrade fast enough to avoid trunk or trunk collar strangulation. Tree wrap should be secured with string or masking tape and removed after the first growing season.

Cords around planting balls should be removed at planting and never left around a tree after it has been planted.

Inspect all newly-planted trees on a regular basis to eliminate problems. Planting wrap on a balled and burlapped tree may be left in place after planting a tree if it is made of biodegradable material, such as burlap. Recently, woven plastic or plastic sheeting has often been used for wrapping balled and burlapped trees. These materials will not break down and will prevent outward movement of plant roots, suffocating the balled tree.

Always remove the cords that tie the ball around the trunk and roll back the wrap from around the trunk. You may leave burlap wraps around the planting ball, but remove all plastic containing wraps from trees when planting.

### Avoiding bark injury

During a recent insect epidemic, many homeowners applied petroleum jelly directly to tree trunks to trap leaf-eating caterpillars, in hopes of protecting their trees without spraying. Petroleum jelly, like many petroleum products, injures tree bark,

Avoid placing any chemicals on tree bark. It is living tissue and will be killed by oil-based paint, grease and oil—as well as petroleum jelly.

PPDs are created by ignorance and lack of concern. By teaching people how they can avoid injuring trees, all PPDs can be prevented.

**Building and road construction are the most frequent causes of injury to trees by people.**
