Table of Control Measures for Major Shade Tree Pests
and lindane has been recommend-
ed for some of the grub types.

**Leaf Miners**

There are many species of leaf miners — elm, birch, and oak leaf miners, to name but a few. Injury resulting from these pests frequently appears as blotches or blisters on the foliage. Partially or completely mined leaves turn brown and are very noticeable.

Loss of leaves is one end result of attack by the birch leaf miner. This damage is usually confined to newly developing foliage. Beyond the second generation, birch miners generally invoke little damage except for such feeding as is necessary to maintain their population. Repeated leaf losses can cause death or weaken the tree, age except for such feeding as is necessary to maintain their popu-
ation. Repeated leaf losses can

be curbed by applications of lindane in the latter part of May for the birch leaf miner, and in early June for elm leaf miners. Treatment with malathion is also effective for control of birch leaf miners.

**Scale Insects**

Because of their small size and general appearance, scale insects are often overlooked until injury has reached advanced stages. This is often the point where it becomes too late to save part or all of the trees attacked.

Scale insects have a tremendous potential for reproduction. Preventive control sprays are advisable in areas where these pests are known to be active from year to year. Treatment with appropriate chemicals should be made on a “planned” schedule, not merely once damage is evident.

Injury caused by scale insects can be extensive, manifesting itself in any of four ways: (1) reduction of growth; (2) abnormal growth; (3) death of the host plant; (4) secretion of an unsightly sticky honeydew substance.

Scale insects are members of a large and complex family. For purposes of discussion, they can be divided into three groups. The first is the covered or armored scale insects, which include such pests as oystershell, euonymus, San Jose, and others. At varying intervals, the young of this species crawl out from under the protec-
tion of the female’s shell or scale. After a short period of activity, they find a favorable location on the host to insert their threadlike mouthparts and feed by sucking the sap. Soon they lose their skins, and, if female, their legs and antennae also. The females combine cast skins with exudations of wax and form them into cover-
ings. After the fourth molt (growth stage), the males soon become minute two-winged insects.

The second type is the naked or soft scale insects. Included here are many such common pests as the cottony maple scale and lecanium species. They are usually humped and resemble the shell of a turtle, are not protected by a separate waxy scale or shell, and perhaps most important, frequently move from place to place while feeding and may crawl back to the twigs in the fall of the year.

A third type of insect closely related to the scale group is the mealybug. Types are too numer-
ous to list at length.

For best results in controlling scale insects it is important that correct identification of the species be made. As with many other pests, timing of spray applications for scale insects is critical. This is especially true with the covered scales where the young come out from under the protective female shells and crawl around. The crawler stage is the best time to
control these scales. Time of spray applications can vary from April through September, depending upon the species and number of generations per year. Recommended materials include Ethion Superior Oil or Superior 70 Second Oil for dormant sprays. Sevin, a malathion-DDT combination, or the Ethion.67 Superior 60 Oil E.C. are excellent choices for foliar sprays.

**Elm Leaf, Elm Bark Beetles**

In recent years many cases of the dreaded Dutch Elm Disease have been traced to the feeding habits of the European elm bark beetle, aided by the widespread and highly destructive elm leaf beetle. It has been found that severe attacks of elm leaf beetles upon the foliage weaken elm trees and make them attractive breeding grounds for elm bark beetles, which we now know are carriers of Dutch Elm Disease.

Large infestations of elm leaf beetles will cause leaves to yellow and fall prematurely. The adult insects are about 1/4 inch long. Those found in spring and summer appear quite yellowish with dark stripes along the sides, while in the fall and winter, they are a more uniform olive green.

European elm bark beetles are reddish brown in color with pitchy, red wings, and approximately 1/2 inch long. The rear portion of their bodies appears to have been chopped off abruptly. These pests feed on small twigs, particularly in the crotches of healthy tree branches. The breeding galleries made by the adult female beetles beneath the bark of weakened or dead trees range from 1 to 2 inches long and contain 80 to 140 eggs per adult gallery.

For effective control of the bark beetle a thorough dormant application is required. As a supplementary measure, a spray in mid-July is also advisable.

In curving leaf beetles, sprays should be applied when leaves are 3/4 grown or as soon as feeding is noted (usually late May or early June). A satisfactory dosage in mid-summer may be needed, particularly if only some of the trees in the area have been sprayed previously.

Couch:

**DISEASES OF TURFGRASSES**

by Houston B. Couch, Department of Plant Pathology, Pennsylvania State University. 1962. 304 pages. $11.00

Consulting Editor: J. Ritchie Couch

"Nearly 100 pages are given over to analysis of turfgrass disease chemicals, and grasses susceptible to ailments. Arranged both by common and technical names, these tables provide a handy guide which could be used by technical directors and serivcemen alike. Couch's new text is more than a handbook, however. In the first 178 pages, the distinguished author delves insistently into the rudiments of both fungus and nematode-incited diseases, and gives valuable pointers on how to tell one disease from another. Another highlight of the volume are the illustrations, both full color and black-and-white, which give vivid reinforcement to the details set forth in the text." — Pest Control

Graham:

**CONCEPTS OF FOREST ENTOMOLOGY**

by Kenneth Graham, Professor of Forest Entomology, The University of British Columbia, Vancouver. 1963. 392 pages. $9.50

Consulting Editor: Peter Gray, University of Pittsburgh.

"Practical uses of theoretical information about the detrimental effects of insects in forests is offered in the latest of Reinhold's biological books... Insects are not treated supercifically; rather, in-depth discussion on the pest and the manner in which it damages trees, whether by boring, leaf mining, or root chewing, gives the student of forestry a sound basis upon which to determine timber loss. A table is included which sets forth the principal insects found in forests and what part of trees they damage. This makes damage detective work simpler... a refreshing, practical slant that pinpoints the study of entomology in the scheme of forest management." — Pest Control

Bennett:

**MANAGEMENT OF ARTIFICIAL LAKES AND PONDS**

by George W. Bennett, Aquatic Biologist and Head of the Aquatic Biology Section, Illinois Natural History Survey, Urbana. 1962. 320 pages. $8.00

Consulting Editor: Peter Gray, University of Pittsburgh.

"The author has included the most recent scientific advances and practical techniques in artificial lake and pond management. For those interested in a comprehensive and integrated presentation of the dynamics and management of warm-water fish populations in artificial lakes and ponds, this is just the book." — Commercial Fisheries Review

**How to spot & control danger** in turfgrasses - forests - ponds

When Writing to Advertisers Please Mention WEEDS AND TURF
slightly in coloring, size, and extent.

Two principal types of injury are usually distinguishable. One is early leaf blight which results in the complete killing of young leaves during April or May. This type of injury varies from partial to complete defoliation of tender leaves and is similar to frost injury in appearance. It is most common on sycamore. The second type of injury shows up later in the season as irregular brown areas adjacent to and surrounding diseased spots on midribs and lateral veins of mature leaves. This type rarely causes serious defoliation, but the fungus may spread through the twigs into younger branches, producing cankers which in turn can cause twig and branch dieback.

As with many other tree pests, successful control by spraying depends on the frequency and the thoroughness of application. A suggested schedule follows:

1. Just before the buds start to swell in the early spring.
2. When the buds are breaking and before the leaves unfold.
3. One or two applications at weekly intervals depending upon the amount of rainfall.

The following treatment is suggested in curbing anthracnose: Puratized Agricultural Spray (a mercury compound spray) — 1 pint per 100 gallons of water applied in the dormant stage followed by 2 treatments of Zineb (2 pounds per 100 gallons of water).

Powdery Mildew
Extensively distributed and occurring on a wide variety of plants, the powdery mildews have distinguishing characteristics which enable specialists to identify them. The powdery mildews are important in this country on maple, oak, alder, elm, poplar, and willow.

The damage caused by this disease is usually slight except when young trees are attacked. The powdery mildews are usually confined to the upper or lower surfaces of leaves, forming a white superficial growth visible to the naked eye. Occasionally, when conditions are right, and the infestation is severe, the mildews will progress onto fruits and twigs of the host. In addition to covering the surface of the leaf, the mildews also produce a sucking organ which penetrates the cells of the host to withdraw food. The spores of the developing mildews are readily carried by the wind and spread the fungus widely during summer months. The fungus overwinters in the black fruiting bodies found on fallen leaves, ruptures in the spring, discharging the spores which are carried by air currents to infest new foliage.

The powdery mildews definitely create an unsightly condition on the leaves of the host trees, but they may be checked during the growing season by use of a sulfur dust or spray at weekly intervals. Burning the fallen leaves in autumn is also quite helpful in a small or confined area.

Leaf Spots
Leaf spots on trees can be caused by insects, toxic gases, bacteria, and fungi. Leaf diseases such as this can be important when defoliation results or when the infestation is so severe that most all the leaves are involved and cannot function normally. Defoliation for several successive years may bring about the death of hardwoods. Species of trees commonly infested by the leaf spot fungi include: elm, chestnut, oak, red maple, hickory, ash, locust, and sycamore.

Characteristic of leaf spot is the formation of dead areas in the leaf. Size and shape of the area can vary from small to large and round to irregular. The deadened tissue varies in color from yellowish to all shades of brown and black. Some of the dead areas frequently fall out, leaving holes (sometimes called "shot hole").

The spread of the leaf spot fungi is basically the same with all species. They overwinter in the old fallen leaves, develop and spread to the newly developing leaves in the spring. Wet seasons favor increased infestations of leaf spot.

Recommendations for control include the burning of fallen leaves in the fall. Dead and cankered twigs should be pruned out before the buds break in the spring. If infestations are severe, spraying with ferban or COCS (copper oxychloride-sulfate) is helpful. Puratized Agricultural Spray (mercury compound) is also useful in the control of leaf spot of walnut, elm, and maple.

Subsoil Problems Blight Laws
Dead spots on lawns or patches that yellow during dry weather may be an indication of subsoil problems, according to Vaughn H. Holyoke, assistant crops specialist with the Cooperative Extension Service, University of Maine, Orono.

Pocket in subsoil, 4" to 8" below the top, can collect water in fall and winter, causing winter-killing, Holyoke explains. "These areas can be the starting point of a severe weed problem, as well," Holyoke adds. In established lawns, turf renovation is the only solution to subsoil problems, so be sure to watch out for it when establishing new lawns, Holyoke warns.
Stauffer's new liquid

SEVIN

4 FLOWABLE

INSECTICIDE

CONTROLS MANY SHADE TREE INSECTS

- May be used in mist blowers, foggers and all other types of sprayers
- Leaves a minimum of visible residue
- Is easy to use safely, less toxic than DDT to fish and wildlife
- Controls insects resistant to chlorinated hydrocarbons
- Controls a wide variety of insects on deciduous and evergreen trees
- Is an extremely fine dispersion of SEVIN in water

For further information and directions for use, write Stauffer Chemical Company, Agricultural Chemicals Division, 380 Madison Avenue, New York 17, New York

*Reg. T. M.
CONTRACT spraying of home lawns and gardens is growing by leaps and bounds. The day is past when the average homeowner can keep most of his pests under control with two or three stock pesticides. Greater insect depredations, a buildup of insect resistance to some spray materials, the wide variety of sprays and dusts, and the recent concern about spray materials have all contributed to take pest control out of the hands of the homeowner and turn it over to the specialist — the contract applicator.

One of many insecticides which operators are now using for a variety of jobs is Sevin, a product of Union Carbide. Being a carbamate, it is unrelated to many older compounds. Chemically known as carbaryl (1-naphthyl N-methylcarbamate), Sevin has a broad spectrum of usefulness and a low degree of toxicity. Spraymen who must handle it are relatively safe from any injurious effects, researchers have reported.

Normal pesticidal precautions should be observed, however. When used according to directions, though, Sevin is not likely to bother customers' children or pets if they come into contact with it on foliage. If it drifts, it will not contaminate crops or harm domestic animals, small game, or fish, when used at the prescribed rates. It is said to be 200 times safer to goldfish, than is DDT.

Formulations Available

Sevin insecticide is available as a 50% wettable powder, an 85% microfine wettable powder, several liquid formulations including a suspension of 4 pounds per gallon of active material (called Sevin 4 Flowable), and 5 and 10% granular formulations, and dusts, each produced by various formulators.

There are some formulating details of which CAs should be informed. To maintain quality of spray preparations, formulations should be mixed accurately and with care. To a partly filled tank with agitator operating, Sevin can be added along with any other emulsifiable formulations desired. While spraying, the agitator should continue operating so as not to let the preparation settle. After spraying, flushing with clean water will eliminate residues.

Separable suspensions of Sevin insecticide should not sit in the tank overnight.

Sevin is compatible with commonly used insecticides such as DDT and other chlorinated hydrocarbons. Compatible organic phosphate compounds include Guthion, malathion, and para-thion. Botanicals are also compatible with the product. Fungicides which may be applied along with Sevin include glyodin, organomercury compounds, fixed cop-
pers, dithiocarbamates, sulfur, captan, Cyprex, and Phaltan. Sevin should not be mixed with any alkaline materials. Bordeaux, lime, lime sulfur, and casein-lime will lessen effectiveness of this new compound.

All common miticides are compatible with the chemical, which is an advantage because Sevin alone does not control certain kinds of common mites.

Sevin controls many insects that have built up resistance to chlorinated hydrocarbon and phosphate insecticides. According to Dr. Edward J. Duda, director of the Bartlett Tree Research Laboratories, Sevin has a good residual effect, and has given up to two and three weeks control of insects such as lace bugs on oaks and sycamores.

Bartlett experts have also had good results using Sevin on birch, oak, and boxwood leaf miners, Japanese beetles (which seem to be moving from gardens into rougher areas), chinch bugs, leaf tiers, tent caterpillars, einkerworms, and periodical cicadas (17-year locusts).

Cicadas were especially troublesome in sections along the East Coast in 1962, and are scheduled to appear over a broad band in the east-central United States in 1963.

**Cicada Control**

Cicadas are controlled by preparing a 2% suspension of wettable powder; approximately a gallon of this is applied to each 50-foot tree. Application should be delayed about 10 days after emergence from the ground; this is the time when female cicadas begin laying eggs in twigs of trees.

Other pests on which Sevin has been successful include bagworms, elm leaf beetles, rose aphids and slugs, lecanium scales, and pine leaf aphids.

Sevin is not only useful on lawns (for earwigs, armyworms, fleas, leafhoppers, millipedes, sod worms, and mosquitoes, as well as chinch bugs), but against insects on home-grown tree fruits, most of the small fruits and nuts, vegetables, rose bushes, garden flowers, and shrubs at 1.0 to 2.0 lb. of 50% wettable powder per 100 gallons of water, or 1 qt. 4 Flowable per 100 gallons of water.

For best results against chinch bugs, lawns in infested areas should be sprayed about the time the young insects are hatching, when temperatures rise into the 70s. One and one-quarter pounds of 85W in 150 to 200 gallons of water will treat 5000 sq. ft. (or 2 lbs. of 50W in the same amount of carrier). This is the same as 1 lb. actual Sevin per 5000 sq. ft.

According to Dr. Louis Pyrenson of the Long Island Agricultural and Technical Institute in Farmingdale, N.Y., best results are obtained when the lawn is mowed and given a good wetting with a sprinkler before applying the insecticide. This brings the bugs to the lawn surface. After application, the turf should be wet down with clear water.

One application of Sevin is capable of controlling an entire generation of chinch bugs. Applications may have to be repeated after 2 or 3 weeks if young of a new generation begin to appear.

CAs who spray flower gardens for insect pests can use Sevin on a wide variety of nonwoody plants including asters, begonias, mums, dahlias, gladiolas, iris, marigolds, orchids, roses, and zinnias. The shrubs include andromedas, azaleas, camellias, euonymus, hydrangeas, laurel, lilacs, rhododendrons, rose of Sharon, and yews, at 1 lb. active ingredient per 100 gallons of water.

On ornamental trees the list includes arbor vitaes, ashes, birches, bamboos, cypress, dogwoods, elms, firs, hemlocks, hickories, junipers, magnolias, pines, sassafras, red-buds, and others. But avoid using Sevin on Boston or Japanese ivy, since it may injure these plants, experimenters discovered.

Sevin poses slight hazard to desirable birds and other animal species, according to James K. Keith, a research biologist with the U. S. Fish and Wildlife Service of the Department of Interior. “Our work to date with Sevin insecticide indicates that it has a low potential hazard to wildlife and that it is one of the more desirable pesticides for use where wildlife values are of consideration,” Keith has stated.
Know Your Species

HOARY CRESS
(Cardaria draba)

Aliases of hoary cress are: perennial peppergrass, hoary pepperwort, and white-top. This alien weed of the mustard family is a perennial which reproduces by seed and by sprouting of rootstocks. It is found in New England, and some mid-coastal states, through the Midwest to the Pacific. Hoary cress seems best adapted to cool climatic conditions such as those found in the Rocky Mountain region.

Stems (4) of hoary cress grow singly straight up, 1-2 ft. tall, branching only at the top. Stems and leaves are hairy. Lower leaves have obvious petioles (stalks) and are spatula shaped with slightly scalloped margins. Higher up on the stem, leaves lose their petioles and appear to clasp the stem (5).

Flowers on separate stalks are arranged in clusters at nearly the same height on the ends of all branches. Flowers are typical of mustards (family Cruciferae), with four tiny white petals in the shape of a cross. As branches grow, flowering at the ends continues; flowers still bloom after lower seeds have matured (1).

Seed pods (2) are heart-shaped, bulbous, attached to the flower stalk at the broad end of this heart-shaped pod. A pod holds two oval seeds, each 1/4 inch long. Seeds are reddish brown and have a rough texture (3).

Roots of hoary cress are slender and many-branched, sometimes penetrating soil to a depth of 10 feet. It is the ability of roots to regenerate tops which makes this weed so difficult to control (6).

Other plants, much easier to control, which may be confused with hoary cress are members of its own family; all have white flowers. Peppergrass, Lepidium virginicum, is not a perennial, is easily pulled up, does not have clasping leaves, and has circular flattened seed pods. Field peppergrass, L. campestre, does have clasping leaves, but they are arrow-shaped (saggitate); seed pods are more boat-shaped.

Pennycress, Thlaspi sp., looks somewhat like hoary cress but has no hair on the leaves and has very flat and rounded pods. Shepherd's purse, Capsella bursa-pastoris, has saggitate, clasping leaves and seed pods are heart-shaped, but they are attached at the narrow end of the pod and are more flattened than those of hoary cress.

Repeated applications of 2,4-D will control hoary cress if applied at the late vegetative to early bud stage of growth. Combinations of leachable soil sterilants such as sodium chlorate, fenac, TBA, boron compounds, substituted urea compounds, and triazines may be used effectively. These herbicides also kill most other plants.

Where sterilization may cause undesirable erosion, planting over with vigorous grasses after application of a contact herbicide eventually controls hoary cress especially with well-timed 2,4-D treatments.

Prepared in cooperation with Crops Research Division, Agricultural Research Service, United States Department of Agriculture, Beltsville, Maryland.

"Industry Hour" to Highlight Fla. Turf Show, Aug. 27-29

New event added to the 11th Annual Florida Turf Conference, scheduled for the University of Florida, Gainesville, Aug. 27-29, will be an “Industry Hour.”

Featured will be chemical and fertilizer products for turf. Each firm that exhibited these products at the Second Annual Trade Show (See Weeds and Turf, July 1963, p. 16), will be eligible to participate. Plans are now being made to continue this event each year, with a new theme being selected each time.

Although final program details and confirmation of speakers are not yet completed, general outline of the Conference will follow those of recent years. “Insects” will be theme of the general sessions, which open Tuesday afternoon, August 27.

Professional discussion sessions will be held Wednesday morning, with sections devoted to golf turf, playfields, parks, and cemeteries; retail dealers and garden suppliers; horticultural spraymen and lawn service agencies; and turf nurseries. Tour of turf plots and a barbecue, with the banquet that evening, will conclude Wednesday’s sessions.

Conference will close Thursday morning, with a general session devoted to 1963 Turf Research Reports.

For more information on the program, or advance registration forms, write to Richard C. Wallace, Executive Secretary, Florida Turf-Grass Assn., P.O. Box 5284, Jacksonville, Fla.

Velsicol Has Bandane Booklet

Information on Bandane, a new pre-emergence crabgrass control from Velsicol Chemical Corp., is available to CAs in a new pamphlet from that firm.

Bandane has a mild selective action, and will not harm seeds, seedlings, or desirable grasses, according to the company. In addition, one application will eliminate ants and grubs from turf for several seasons, Velsicol claims.

For more information, write to the company at 320 East Grand Ave., Chicago 11, Ill.
Get full protection...full vision...comfort...with Acme Gas Masks

There are a lot of things you'll like about an Acme Gas Mask. For example, you'll like the full protection that guards your face and eyes. And you'll like the Acme's Full-Vision Design. It lets you see more than any other mask. (Ask for Visionscope Proof.) You'll breathe easier too. That's because our large Inhalation-Exhalation Valve is designed for minimum resistance. This adds to your comfort. So does the special soft-but-durable rubber we use for the face piece.

For “proof of the pudding,” try an Acme Mask. Call your distributor. He’ll be glad to demonstrate. Or...

Ohio Shade Tree Conference Laments Severe Winter and Hot, Dry Summer

"Because of a tough winter, which caused us to lose a lot of young trees, and the current drought in the Midwest, we're having a hard time of it," John Michalko, Commissioner of Shade Trees for the City of Cleveland, told delegates to the Ohio Chapter of the International Shade Tree Conference.

Nearly 800 arborists, tree company supervisors, and utility foresters gathered July 10 at the Cleveland Municipal Shade Tree Headquarters for the annual meeting, which featured tours of outstanding tree plantings in the Cleveland area, and a demonstration of some new tree maintenance equipment.

Michalko's remarks preceded a report from Dr. L. C. Chadwick, secretary of the Ohio group, who reported that the Buckeye tree organization, with a membership of 191, is now second in size only to the California chapter.

During the business session, chaired by president George Kase, of the Cincinnati Park Board, delegates voted to incorporate the Ohio chapter.

After the equipment show, the Ohio treemen moved to the Cleveland Museum of Art for additional talks on the role of tree personnel in urban redevelopment.

"There used to be a conflict between municipalities and electric companies over trees," Lee Howley, vice president and general counsel of the Cleveland Electric Illuminating Company, told the assembly.

This conflict is being resolved, however, through such programs as CEI's Master Tree Plan, which helps municipalities plan tree plantings which will not interfere with utility lines, traffic, or sidewalks and sewers, and which will still enhance the esthetic character of a city's neighborhoods.

Next meeting of the Ohio Chapter will be in the last week of January in Columbus. Exact dates will be announced later, Dr. Chadwick told *Weeds and Turf*.

International Shade Tree Group Has Varied Convention Program

A program designed to satisfy tree specialists from all phases of the industry highlights the 39th Annual International Shade Tree Conference this month in Toronto, Ontario, Canada.

Nearly 800 delegates are expected to register during the 6-day tree seminar which runs from August 4 to 9 at Toronto's Royal York Hotel.

Much of the program is devoted to discussions of tree pest control, including talks on non-infectious tree diseases. Moderated by Dr. Spencer H. Davis, ISTC vice president, these tree ailment talks include "Ash Dieback in the Northeast," "Maple Decline in the Northeast," and "Sweet Gum Blight."

Role of tree surgery in modern arboriculture is the subject of an address by C. L. Wachtel, Wachtel Tree Science and Service Co., Wauwatosa, Wis.

Concepts of soil aeration and the relationship of this process to tree growth are being examined Monday by George Yelenosky from the Department of Botany, Duke University, Durham, N. C.

Split sessions are scheduled for Tuesday to better accommodate the varied interests of conference delegates. In the series of talks geared to members of the National Arborists Association, markets and public relations are covered.

"Shade Tree Spraying — the Tree, the Public, the Arborist" is the title of a talk by Henry F. Davis, Lowden Tree Specialists, Inc., Needham, Mass. "New Markets for Tree Service" is being presented by Robert Felix, Harder Tree Service, Inc., Hempstead, N. Y.

Also on Tuesday, those interested in municipal arboriculture may attend discussions chaired by John G. Michalko, chairman of the ISTC's Municipal Arborists Committee.

A significant talk on the real facts behind pesticide usage, presented by Dr. George C. Decker, distinguished entomologist of the Illinois Natural History Survey, Urbana, is in the offing Thursday.

A detailed report of the conference will appear in W&T next month.
