What is there to weed control besides just killing weeds?

Maybe the area to be treated is already weed-free. Or maybe it's infested with established weeds. Perhaps the weeds are annuals. Or deep-rooted perennials that ordinarily are more difficult to control.

Could be the area is large. Or small. It may be easily accessible. Or it might be difficult to reach, either with sprays or big equipment.

These, as well as moisture availability and soil type, are just some of the conditions you have to consider before selecting a herbicide.

But whatever the weed problem, you'll find the right answer in one of the five Geigy industrial herbicides. Why? With them, you can solve just about any weed problem you might encounter.

What's more, each Geigy industrial herbicide delivers long-lasting residual control with once-a-year application. So they're most economical, too.

Geigy herbicides are easy to handle and apply. They require no special protective clothing or devices and can be applied through most application equipment.

For spraying, you can use Atrazine 80W or Simazine 80W wettable powders, or Pramitol® 25E emulsifiable solution. Where spraying is impractical, you can apply dry Pramitol® 5P or Atratol™ 8P pellets, by hand or mechanical means.

Find out more on how these Geigy industrial herbicides can solve practically all your weed problems . . . effectively and economically.

Be sure to write us today for fully descriptive literature.

CREATORS OF CHEMICALS FOR MODERN AGRICULTURE
the sand. The greens were planted with Penncross bent grass.

On the fairways the turf was stolonized with Tifway #419 hybrid bermuda and the roughs were seeded with Kentucky blue grass applied in a slurry mixture. The erosion banks were also seeded with the slurry technique.

Germination of the planted turf was an early test of the irrigation system and started June 4, 1967. This crucial period extended through late August. The stolonized turf required roughly 4 times the normal amount of water to maintain an existing turf, and the dependability of the Buckner system proved itself in the resulting turf.

On greens and tees, periodic misting of the areas proved most successful according to Superintendent Little. The system was set to operate during all the summer daylight hours. Little chose to irrigate 2 minutes per hour each day through the germination time, and has reaped a gourd-green, healthy turf from his precisely controlled irrigation.

After the course is open for play, the adaptability of the Buckner Irrigation System will be extremely valuable again, according to Little. Quick economical adjustment of irrigation control can be made easily to meet watering requirements of the course according to the amount of play it receives, mowing schedules and the quality of play. Initial plans call for watering greens every night and fairways every other night.

Trees were planted throughout the course from existing trees on the property. There were many conifers - some 25 feet high—and some were a backdrop for Robin Hood in the films of yesterday.

Nursery trees, eucalyptus, flowering plum, liquid amber, and varieties of oak were also planted as part of the overall landscape design. Along with the lush fairways, greens, tees and roughs they create a green carpet that reaches to rugged background hills. Calabasas Golf Course is truly a magnificent example of the results of combined expert design, irrigation and installation technology in the west.

to 3000 golf course superintendents
at the GCSAA 39th International
Turfgrass Conference and Show

Cost Analysis:

Garold M. (Jerry) Murphy, superintendent, Somerset Country Club, St. Paul, Minn., reported on the 1967 conversion of a quick coupling system at his club to an automatic Toro Vari-time satellite system.

For GCSAA members, he presented an analysis of the costs and general operating experiences with the new system. His own time in operating the new system requires 5 to 10 minutes once or twice weekly. This is spent adjusting the master controller to adapt to changes in weather and spot checking of satellite control dials.

Sprinklers for the system are gear driven and make the complete revolution in 3 minutes. This, Murphy pointed out, is adequate for relief of stress under the Somerset course conditions. This also permits timing syringing to suit play and results in minimum interference with golfers.

Operating costs presented in the table include electricity and lubricant for the pump and gas and lubricant for the patrol vehicle. It does not include repair or depreciation. Cost for the 2 systems is comparable. The slight difference in favor of the automatic system probably is valid, since night watering can be completed in 12 hours as compared to the 14 hours formerly needed with the quick coupling system. Major operating cost, Murphy said, is for electricity.

Some cost benefits of the automatic system are difficult to assign a monetary value, Murphy reported, but they do exist. He enumerates them as turf benefits and as people benefits. He suggested that superintendents might assign their own dollar value to these (Tables II and III).

In general, Murphy said, the savings in labor and operating costs are significant and impres-

6. More favorable comments on condition of golf course.
7. Peace of mind—Superintendent.

Irrigation System Design:

Chances are, when you invest in an automatic irrigation system you are going to pay the same price as a good, well planned system would cost. Why not insure that you will get what you pay for? This is the opinion of Richard R. Abernethy, Telsco Industries, Dallas, Tex.

Abernethy, in presenting the official GCSAA Golf Course Irrigation questionnaire to GCSAA members for help in planning and designing custom irrigation systems said that the trend today is toward “turnkey” design and installation. This type system, he said, is done by competent, specialized golf course contractors. Such firms today are well capitalized, employ engineering personnel for both design and construction supervision, and have the specialized equipment to do the job right.

Tremendous responsibilities are placed on the superintendent by members and directors for the success of a system which is a major investment. Abernethy points to the questionnaire as a means of covering, in practical language, all the major areas necessary for the irrigation designer to prepare an authentic, accurate and practical estimate of individual irrigation needs.

No one knows the course better than the superintendent, Abernethy implied. He pointed out that water requirements vary from one geographical area to another. Fairways, greens and tees require special consideration, especially for drainage and wind problems. Only the superintendent knows how often the course requires hand or supplementary manual watering. Thus, he believes that the questionnaire provides the “common denominator” which will enable the superintendent to (1) better evaluate the job, (2) communicate the facts to the decision making administration, and (3) better understand the finished product or design when the final plans are presented for approval.

This approach, Abernethy said, can save money.

Primary Decision Making:

Engineer Don A. Hogan, D. A. Hogan & Associates, Seattle, Wash., presented the 3 common approaches to the problem of golf course irrigation design and installation and the problems associated with each. First, Hogan said, is the “package deal” or the “turnkey job.” This is attractive, but Hogan pointed out, leaves the club somewhat vulnerable because the seller determines amount and quality of work and material, while the owner does...
Chinch bugs don't stand a chance when you hit them with Ethion. Ounce-for-ounce, no other pesticide can match its Chinch-killing power.

Spray lawns with Ethion, and grass is safe for six weeks or more. You'll be safe, too. Ethion isn't a dangerous chemical. Just use normal precautions. See your favorite supplier for a selection of Ethion-based sprays. They make Chinch-killing a cinch.

Ethion®

It's a cinch to kill Chinch.
For Turf Care!
One of the handiest sprayers a professional can own. Ideal for jobs too small or too irregular for power equipment. Sprays either a 48" wide or 24" wide swath. Unique rubber wheel-pump "milks" out solution as you push the sprayer. Lays down a heavy residual spray. For killing weeds. Fungus control. Insect control. Turf grubs. Fertilizes, too. Safe. Sure.

not have an experienced person protecting his interests. Normally, design and materials are limited to a single representation. And, Hogan said, it is not probable that architectural professional ethics can be completely divorced from the influence or effect of the contract profit aspects.

The second approach is the combination of design and materials supplied by one firm and a separate contract for installation, or where the owner installs the system. This method, according to Hogan is normally less costly. Here, again, he said, lack of construction coordination may result unless the owner has an unbiased, experienced representative to supervise and coordinate the project. The term "design" as applied usually covers only a simple drawing or layout. Other engineering requirements must be performed in conjunction with the basic layout.

The 3rd approach by Hogan was the professionally designed system by a qualified engineering firm, combined with the installation being performed by the successful bidding contractor. In this case, the contractor's work is supervised and inspected by the engineering firm who represents and protects the interests of the owner. Hogan, an experienced engineer in the business, believes a private engineering firm paid directly by the owner is the best arrangement.

The team approach, in the belief of Hogan, can result in the most satisfactory system. He lists team members as follows: (1) club committee, (2) golf course superintendent, (3) professional designer, (4) installation contractor, and (5) material suppliers.

Each member group on the team needs specific qualifications and has definite responsibilities, Hogan said. The club committee is first. This group needs to be dedicated and willing to devote time and effort. They must work directly with the golf course superintendent and engineer.

The golf course superintendent is a vital team member. His knowledge of the course and turf management will influence the type of system to be approved. He must present operating costs in conjunction with the engineer, work out completion schedules, and see that future plans of the course are in line with the new system, plus a myriad of other details which must be coordinated with the entire team.

The 3rd member of the team, the professional designer, must work closely with the club committee and superintendent in a detailed design. This will include all construction details and specifications, prepared for bidding and construction control purposes. He must screen bids, approve materials, monitor construction work, and perform necessary tests, in detail, of the installed system. Finally, upon completion, he must certify the installation and furnish operating instructions and "as-built" drawings.

Job of the contractor as a team member is to install the system in a workmanship manner in complete accordance with the specifications. He must use quality materials and equipment, and supervise the project, at the same time working closely with the superintendent to familiarize him with operation and maintenance.

Material suppliers must provide data on materials and equipment, assist the contractors in bidding, coordinate delivery of materials, instruct the construction crew, assist in final adjustment and testing, and generally service their products.

Because of the magnitude of the modern irrigation system, Hogan pointed out that it warrants the best possible development. It is a serious mistake, he said, to settle for less.
Tree Planting Review

check list
for new employees

Tree Care men have to answer lots of questions. During tree planting operations, passersby and buyers become literal sidewalk superintendents. Questions as to why mediumsized and dwarf species are best for streets and ranch-type homes need answers. This is good for the industry.

At the same time, the tree man must be prepared to astutely discount the value of old, favored, but less desirable trees. For example, he must explain why Chinese and Siberian elms, poplars, willows, silver maple, boxelder, and others are not suitable. Though fast growing, they are relatively short-lived. Also, their brittle wood is susceptible to storm damage, roots invade underground pipes, and they are subject to pest and disease attack. A learned explanation assures the onlooker and promotes the professional care business.

Further, careful planting can build business. It does much to increase the percentage of trees which survive a move. This is especially true of wilding trees. Nursery stock is usually much easier to handle.

Most tree men prefer nursery stock, either that grown by themselves or purchased from a reputable operator. Nurseries generally offer a large selection of sizes and species. When compared to wilding trees, the nursery trees will have better root and crown systems, will become established more quickly, and are more likely to live.

When wilding trees are used, they need to be dug in open rath-

---

**Diagram Instructions:**

A. Well developed head with strong leader, branches set at wide rather than close angles.

B. Before setting, tree should be pruned at points indicated by black lines rather than clipping the ends of branches.

C. Base of permanent crown should not obstruct walks or roadway.

D. Loop brace needs to be loose, pliable. Remove after the tree becomes firmly established.

E. Stake, 2½ inches by 10 feet in height, needs to be driven into ground and secured with rubber covered wire or canvas.

F. Preserve all fibrous roots possible. Remove broken roots with a clean cut.

G. Dig hole at least 2 feet in diameter and 18 inches or more in depth.

H. Fertile soil needs to be packed firmly about roots and the hole filled to original soil level on trunk. Keep the soil surface pulverized.

J. Set tree 2 inches deeper than it was originally in the nursery. Fill hole to the lower root level with a 3:1 mixture of good soil and peat moss.
Functional Tree Parts

A. Crown.
B. Leaves. With sunlight these convert carbon dioxide from the air plus "raw" sap into usable food.
C. Pith. Located at very center of trunk. Composed of tissue which is produced at the growing point of the elongating stem.
D. Trunk. Provides mechanical support for crown and transports water and nutrients plus storing food manufactured in leaves.
E. Heartwood. Composed of dead cells and main function is support.
F. Sapwood (xylem). Conducts "raw" sap from the roots to leaves. Consists of both living and dead cells.
G. Cambium. Located between sapwood and inner bark or phloem. Composed of a thin, continuous layer of cells. Produces new wood and bark.
H. Inner bark (phloem). Conducts usable food from leaves to the cambium to nourish tree or to storage areas in the wood.
I. Medullary rays. These store food and conduct water and food laterally.
J. Outer bark. Composed of dead cells. Insulates and protects inner tissues from disease, infections, and drying.
K. Roots and hair roots. Hair roots absorb water and mineral salts from soil. Larger roots anchor tree and store nitrogen and carbohydrates.

Large Trees Can Be Successfully Transplanted

For even larger trees, those with basal trunks of more than 3 inches, root-prune for 2 years and move the 3rd year. In the first year, root-prune only part of the way around the trunk. Do the final root-pruning the 2nd year and then move the tree the next season. Though this is seldom practical, it is safest and will pay dividends in livability.

Evergreens are dug the same as hardwoods, making full use of the soil ball. However, evergreens need not necessarily be root-pruned prior to digging. When moving trees with a soil ball, work burlap well up and around the ball. Tie the burlap at the top of the ball so that it holds the soil securely in place.

Hardwoods may also be dug with roots bare. When this is to be done, dig around the tree carefully and cut the roots. Use a spading fork to loosen soil. Do this by gradually working the soil away from the roots. Start at the outer edge where the cut has been made and work toward the tree. In moving trees with bare roots, place peat moss and burlap around the root system. In all cases, keep roots moist until planted.

Best tree planting time is spring, during the dormant stage.
The Mitts & Merrill Brush Chipper . . .

most efficient way to reduce branches, limbs, brush

These exclusive features:
• Staggered knife pattern . . . means more cuts per revolution, smoother cutting action, smaller chips of uniform size (reusable as mulch)
• Swing-away chute . . . permits quick and easy access to cutting chamber
• Reversible knives . . . give you twice the service between sharpenings; also self-adjusting with positive lock pin to prevent throw-out
• Heavy duty construction . . . coil spring, torsion type suspension; all tubular steel trailer frame
• Torque converter . . . available on all models

The Mitts & Merrill Brush Chipper makes the job of tree removal faster, easier and safer. Every feature . . . from the easy-to-load feed chute to the adjustable discharge chute . . . is ruggedly built and simply engineered for peak operating efficiency and minimum maintenance. Choose the chipper that's first-choice of municipalities, public works, highway departments, tree and nursery men. For complete information and list of specifications, contact the dealer nearest you or write us direct.

There's a Mitts & Merrill Brush Chipper dealer near you — ready to serve.

HI-RANGER

HI-RANGER® IS

... your most productive, safest aerial platform for fastest, easiest tree service. Self-leveling bucket with one-hand, "3D" all-direction control enables one or two men to maneuver while operating tools.

YOU ARE

... assured of maximum work accomplished by happy crews who appreciate the safety inherent in HI-RANGER® insulated bucket and upper boom. Available with "all-day" chipbox. HI-RANGER's Series 5TD is most popular with tree men. Get all the facts now.

before the buds break. Trees are also easily moved during fall months, from leaf-coloring until freezing weather.

Once dug, trees need to be planted as soon as possible. When stock cannot be planted immediately, it needs to be heel ed in by setting roots or soil ball in a hole, covered firmly with soil and kept moist.

Planting sites are important. Street trees do best when planted inside the sidewalk, rather than between walk and curb. The exception to this, of course, is when there is a wide area available between walk and curb.

Before planting, carefully consider the size of the fully matured tree. Trees need to be set 30 feet from structures and 50 feet apart. Make the hole deep enough and with sufficient width to receive the root ball without crowding roots. It is wise to dig a larger hole than needed and to refill excess space with a mixture of well-rotted manure, compost or peat moss, and rich loam. Trees need to be set about 2 inches deeper than they were in their original site.

When planting, remove bur lap from ball or lay it flat in the hole. Spread all roots in a natural position. When this is not done, girdling roots may result and kill the tree. Jagged, broken, or badly injured roots need to be cleanly cut above the injury. Save as many small, fibrous roots as possible. Fill the hole in steps with a mixture of soil, rotted manure or peat moss. Tamp slightly and water as more fill is added. This forces soil around the roots and prevents air pockets. Leave a small depression around the tree to catch as much water as possible.

Stake the tree with loops which are attached loosely. Canvas or other pliable material such as a section of rubber hose works well. Do not use anything which will injure the bark. Commercial loops can be purchased. Also, a recheck to see that stakes are holding the tree in a rigid position is worthwhile. Water as conditions warrant.

In the case of hot or particularly drying weather, the prepared anti-drying mixtures or waxes may prove profitable. These permit the tree to become established without too much drying out.

Hardwoods Need To Be Pruned Before Planting

Top-pruning is a must for hardwood (deciduous) trees. This offsets root loss which results from digging and moving. Nursery trees, because they have been root-pruned prior to digging, need less pruning than wilding trees which are dug and immediately planted.

Pruning needs to be distributed over the tree rather than just removing the ends of all limbs or removing all the branches on the lower half or third of the tree. Remove interfering limbs. Space limb crotches so that plenty of space is left for each remaining limb. Cuts should be flush for rapid healing of pruning wounds. Never cut back the leader unless one of the laterals in the top whorl is also removed. Otherwise, an undesirable forked tree will result.

Evergreens are seldom pruned except when root loss is severe. In such cases, remove some of the past year's lateral growth. Do not prune off entire limbs on evergreens or the natural form of the tree will be destroyed.

Recommendations for this WTT Tree Care Report are based on technical material of the Maine Forest Service. Illustrations likewise are based on Maine recommendations for planting and care of shade trees and supplied by Maine State Entomologist Robley W. Nash, Augusta.
