AQUATIC WEEDS

By JACK MURNIGHAN
Manager, Aquatic Division
Pennwalt Corporation

AQUATIC weeds, pond weeds, or lake grass—water junk, scum or flotsam—alligator weed, chara, hydrilla or hyacinth, call it what you like. Unwanted aquatic weeds and algae are increasingly prevalent throughout the United States . . . and represent a potentially large and viable market for professional applicators.

Three major factors must combine to create a market—a body of water, aquatic vegetation and people who want or need to use the water. Water, weeds and people. Market potential is everywhere. But, so far, we've only seen the "tip of the iceberg."

Commonly, the market is identified as lakes and ponds used for recreation and fishing. Only in Florida and other selected southern states has real interest been generated for other purposes—specifically, control of aquatic weeds and algae in flood control and irrigation canals.

Water weeds and algae create a number of problems. In recreational and fishing areas, they limit boating and swimming enjoyment, tangle fishing lines and may create an imbalance in fish populations. In farm and industrial uses, they may reduce the holding capacity of the lake, pond or canal by as much as one third, restrict or clog irrigation equipment, and lower the efficiency of cooling towers and pumping equipment. And in almost all cases, when allowed to grow, they become smelly and ugly eye-sores, reducing property values. Also, algae and aquatic weeds provide a home for mosquitos and other insects.

The market, then, is certainly not limited. The key seems to be identifying it within your local area. Some of the places to look include: lake associations, estates, farm ponds (irrigation or recreation), forest preserves, resorts, lakefront property owners, fee fishing lakes, hatcheries, golf courses, camps, flood control districts, real estate developments (with man-made or natural lakes), dairy and feedlot operators (with settling pond requirements), water companies (private & municipal), industrial companies with cooling towers or water emphasis landscaping, rice farmers, marinas, and irrigation districts.

Obviously, the market opportunities vary in different geographic regions. The Great Lakes region has a high number of weed-infested lakes. Southern California has, perhaps, the greatest number of golf courses with water-hazards per capita in the United States. Florida has a great number of flood and irrigation canals while parts of Idaho and Washington have some of the largest irrigation systems in existence.

Pennwalt Corporation, one of the major manufacturers of aquatic weed control herbicides, is seeing sales trends shift from primarily the recreational lake and farm pond markets in the north-central United States and Florida to more diversified markets throughout the nation.

Why go into a business of this type? Profit! Also, the professional aquatic vegetation control operator is in very short supply. As an adjunct to an already existing professional herbicide applicator, it becomes an added service to offer customers and a further means of applying already existing equipment and technology.

Control of aquatic weeds is generally achieved through one of three methods; mechanical, biological and chemical.

Mechanical cutting, or pulling, is generally very short-lived. Plants frequently return within weeks. Dredging or drying up the canal or pond and scraping it clear can be effective, as these processes eliminate fertile deposits and deepen the canal or pond. Unfortunately, this cannot always be done.

Mechanical harvesting equipment is available for large operations. It is expensive, often inefficient and slow. Further, it frequently spreads the weed infestation as it drags cut weeds from one part of the lake to another. Finally, the "cut" weeds and algae must still be disposed of—frequently by the truck-load. Labor also is a very costly factor. With practically all mechanical aquatic weed control methods, the cost of efficient control is too expensive for practical use.

Biological methods for controlling aquatic weeds have been popular in concept over recent years. Biological control takes many forms. The primary biological methods of control has been to stimulate the growth of natural weed and algae enemies; stocking these water bodies with plants, fish, or other microorganisms that will attack the undesired vegetation. In our opinion (continued on page WW)
THE United States Department of Agriculture reports that there are 10-million acres of turf in this country. This figure doesn't include home lawns. These 10-million acres are industrial turf, apartments and condominiums, hotels and motels, all types of government installations (from office buildings to military posts), Federal and state highway rights-of-way, parks and recreational areas, sod farms, athletic fields, schools and colleges, hospitals, airports, cemeteries, and railroad accesses.

In short, there's a lot of ground surrounding a wide variety of facilities. Some of this turf gets a lot of care, while other turf simply is mowed. Many property owners have their own crews to apply herbicides and do landscaping work. Other owners turn to custom application firms to get the job done. So, there are not only a variety of different types of turf sites; there also is turf where you may not tread.

In general, the custom herbicide application market is in the densely populated areas of the United States, regardless of what part of the country. This excludes, in many cases, the inner city of urban centers. The amount of expendable income—either by the homeowner, business-man, or government—is a major factor in turf care. Income levels often are reflected in the quality of turf.

Now, let's look at the major categories (or market segments) for custom herbicide application. The first category includes golf courses, sod farms, and athletic fields. Many courses have staffs that apply herbicides, mow, and do other chores. However, upcoming state and Federal pesticide applicator certification programs (some states already certify applicators) may make it possible for knowledgeable applicators to take over some golf course work. Athletic fields may be small, but certain schools expect them well cared for. The lifeblood of sod farms obviously is not weeds. The need for exact chemical application is important here, too. Some sod growers have chemicals applied by air; so there is a need for highly specialized equipment here.

Home lawns are a new area for the custom applicator. New application firms are springing up quickly around the country. These firms are making four or five applications (fertilizer, herbicide, insecticide, and fungicide) annually, so spring is not necessarily the only peak season for the home market. Also in this second category are apartment complexes, condominiums, and industrial firms that are proud of their outward appearance. The latter three also may desire full landscaping services (mowing, pruning, etc.) in addition to herbicide application. Because the acreage is not large for any potential customer in this category, you need a number of customers to maintain a profitable business.

In group three are industries that want a nice—but not great—turf. They've some money to spend, but not a lot.

Opportunity in group four is, perhaps, the most limited. This group includes airports and highway rights-of-way. Airports generally want only to keep weeds away from runway lights and off the edges of runways. Total-kill products are most often used here. Herbicide application on highway rights-of-way is usually done by the government. However, a private applicator pops up every so often. Profits are lowest here, and it's probably the most difficult segment of the market to penetrate.

Not related to the above is total vegetation control (TVC). Railroad
sites, certain industries, utilities, and highways need this service. However, make certain you want to invest in the special equipment required for this type of custom application.

To be sure, there is a good market for custom herbicide application. However, you must concentrate on the treatable acres. Don't let the 10-million-acre figure mislead you. Probably significantly less than half of this land is ever treated for weed control.

As with most businesses, there are good firms and there are less competent ones. You've probably heard of some outfits that spray with nothing but soapsuds at a charge of $25 or use the wrong chemical for the job. Whether you intend to seek new customers for the custom application business or replace firms now treating turf, you must offer expertise and service. This knowledge sets you apart from applicators who do not know their business.

Expertise should be a vital part of your operation. You need to know the best time to apply chemicals, weed identification, proper rates for the herbicides you use, and the type of equipment best suited for each job. Knowledge and compliance with Federal and state laws and requirements fit into your expertise.

And, liability coverage is as important for you as it is for any businessman. Herbicides may drift to nearby ornamentals and other desirable plants even under ideal situations. Poor attention to proper rates also can destroy turf and surrounding vegetation. Experts value their reputation and their customer. They have liability coverage.

Doing things the right way must have an advantage. A recent survey by this magazine revealed that 10 percent of the applicators do 60 percent of the dollar volume. Expertise is the key. Your customers want and need to depend on your knowledge.

Your expertise is reflected in the herbicides you use. Are they liquid or granular, or both? Experience has shown that profit potential is about the same for either formulation. This decision and that of market segment are governed by the type of weed control you offer. The types are preemergence, postemergence, selective, or TVC.

This is a good time to mention that a close working relationship with chemical firm representatives and people from chemical dealers is most beneficial. Their knowledge of the market in your area and of their chemical products can help you in making your choice of granular and liquid products and, eventually, equipment to apply them.

Proper equipment is essential. Spray rigs used for home lawns are of little value for golf courses because the acreage is too great. Handgun sprayers are far less accurate than boom sprayers. Booms offer more uniform chemical concentration and reduce the chance of overlapping where two, three, four, and even five times the normal application accidentally may be made.

If you're treating industrial turf, you probably will need a tank sprayer ranging from a 100- to 500-gallon capacity or a large crop or rotary spreader. Because of the rough terrain around many utility sites, a four-wheel-drive vehicle is best. You also may be applying other chemicals, such as fungicides and insecticides. It is necessary, then, to purchase equipment suitable for applying different types of chemicals.

Your customers' acreages can guide your equipment decisions. Many applicators design their own rigs or modify commercial equip-

The Herbicide Market

HIGHWAY WEEDS

By A. PETE NICAS, Manager
Industrial Herbicide Sales
Agricultural Division
Ciba-Geigy Corporation

IT IS ESTIMATED that 25 percent of all herbicides sold in the U.S. for non-agricultural uses are utilized in highway and roadway programs. Contact and selective herbicides are applied to more actual acres than residual or soil-active herbicides. However, the latter group of herbicides which are used for bare ground applications equals the market value of contact and selective herbicides combined.

Selective vegetation control involves general or spot application of herbicides on roadsides for brush, broadleaf weed and noxious weed control. These treatments provide the following benefits: (1) Improved visibility for drivers; (2) Removal of vegetation that is detrimental to crop lands, livestock and humans; (3) Acceptable levels of desirable grassy vegetation along with protection from wind and water erosion; (4) Improvement of aesthetic values.

Residual or soil active herbicides yield bare ground around shrubs, trees, shoulders, guard rails, pavement cracks, sign posts and delineators. With the exception of erosion control, residual herbicides provide the same benefits as selective herbicides. They are also used to prevent vegetation from destroying paved surfaces.

Compared to mechanical or hand methods of vegetation control, proper use of herbicides generates significant cost savings and provides more effective control of vegetation in most situations.

There is a general increase in the use of residual herbicides on highways. And the trend is expected to continue for the following reasons: (1) Rising labor and machinery costs; (2) Fuel shortages and/or rising fuel costs are expected to generate even more interest in chemical vegetation control as a replacement for mechanical methods; (3) More interest in highway beautification; (4) Increased interest in landscaping with ornamentals and ground cover will continue to increase the need for weed control to insure aesthetics and survival of desirable species; (5) Development of new products; (6) Increased manufacturer and highway department knowledge in the areas of product and application technology.

Most highway herbicide applications are made by the maintenance departments of the various highway departments. Biggest exception is in the Midwest where numerous counties and a few states contract all or part of their application work. Custom applicators, weed control specialists and tree maintenance companies share in the contracted market which is estimated to account for less than a fourth of the national expenditure for herbicides used on highways and roads.

For the independent applicator it appears that the best way to break into the highway market may be to approach a county or township highway department that is not doing any highway weed control. In other words, go to someone who hasn't done it before and explain what you can do.

Ed Edwards, owner-operator of Edward's Spraying and Construction, Clear Lake, Iowa started doing that 26 years ago. His first contract was with the highway department of Polk County (Des Moines area), Iowa. Since then his business has grown to where Edwards services more than 40 Iowa and Minnesota counties.

"I first saw the need for this type of service about 30 years ago," Edwards recalls. "County highway crews were doing the brush and weed control as well as all their other maintenance work. Road repair and maintenance demands were usually heavy in early spring — the time when weed control applications should be made. Often they got caught short of time and it was difficult for them to get applications made at the optimum time for control."

After touring several states to learn what others were doing in industrial and roadside weed control, he developed a program and presented it to the county highway department.

"We emphasize application," Edwards says. "That's our specialty. There are a lot of good products available to fit any particular need — Pramitol, for example, is good for right-of-ways where no vegetation is wanted."

Beyond the business expansion potential offered to horticultural and industrial contractors, highway work offers opportunities for agricultural applicators. These applicators already have much of the equipment and knowhow required, and some firms are finding highway work a good way to utilize idle equipment and personnel during part of the off-season. One such firm is Auburn Fertilizer and Chemical, Auburn, Illinois.

"Usually by the time bids have to
be placed for state jobs — March-April — we have an idea how much time we'll be tied up with fertilizer application," says Joe Powell, applicator. "If fall weather allowed completion of most of it, we try to get some highway weed and brush control work. It offers good margins and a chance to utilize idle equipment and labor."

Based on our experience in highway weed control we estimate that per mile herbicide expenditures range from as little as $2 to as much as $21. Selective herbicides find widespread geographic usage while the larger use of sterilents and contact herbicides is found mainly in the south where Bermuda and johnsongrass are serious problems.

Ciba-Geigy herbicides are used extensively for highway weed control. Because of their broad control spectrum and universal geographic adaptation, their popularity continues to increase.

Pramitol is used primarily for controlling hard to get perennial broadleaf weeds and grasses. This product in combination with Princep provides control of both deep-rooted perennials and late-germinating broadleaf weeds and grasses. A new use for Pramitol 25E that is growing rapidly is in combination with asphalt cutbacks to prevent degradation by weed breakthrough after they are applied on shoulders, on cracked asphalt surfaces, country roads and under highway fences and guard rails. This treatment extends the life of the new surface resulting in considerable savings in time and labor.

Princep is a broad spectrum herbicide that is particularly effective in controlling shallow-rooted annual weeds. An additional asset is its safety to desirable trees, shrubs and some ground covers. Princep is used extensively for weed control around ornamental plantings and in highway spray programs where safety to deciduous fruit and nut trees and/or citrus is an important consideration.

AAtrax and Atratol (AAtrax plus Pramitol) are also used for highway weed control, especially in the Pacific Northwest.

Private applicators have the tools and knowledge to tap this large potential market. They have the skills necessary to meet the growing and increasingly specialized demands of highway work and the modern herbicides to fit virtually any job requirement. With the added benefit of being able to keep expensive equipment working more of the time, highway weed control appears to be an area the applicator should investigate as a means of expanding his business.

AQUATIC WEEDS
(from page SS)

biological controls have simply not been proven effective. They may create a different nuisance than the one they were employed to control, and in turn, require additional control measures.

Chemical herbicides have proven the most practical. Comparatively, they provide low-cost aquatic weed control with minimum labor. The algae and aquatic weeds are killed and decompose, eliminating the need for physical removal to another site, or the need for additional control measures. In many cases, they are the only means of economic control — for example, in a dry, hot western summer where continued irrigation is mandatory for healthy crops.

There are a variety of aquatic herbicides available produced by various companies including Chevron, Dow, Pennwalt, Shell and 3-M. Some of these companies offer aquatic herbicides with several variations effective on nearly all aquatic weeds and algae found in water environs.

Perhaps it is prudent, at this time, to point out that there are aquatic weed control chemicals — and chemicals that kill water weeds, algae and other vegetation also. Water is a life-source of the human — yet, all too frequently, chemicals known to have toxic residues on fish and/or humans are used against water weeds and algae.

Sometimes these chemicals are also effective against other useful vegetation — and have been known to kill valuable economic crops many miles "down-stream" from the point of application. The EPA (Environmental Protection Agency) and many states have laws or controls applicable for use of herbicides in such water bodies. In many states, application of aquatic weed and algae control chemicals may only be applied by licensed applicators. In others, permits must be obtained. In still others, no legislation exists. And, of course, there exist various combinations of the requirements. Most professional herbicide applicators are aware of such laws in their states — but it is always wise to check.

The season for aquatic weed control exists from three months to year-round — depending on geographic region and the nature of the market. Summer weed control is particularly prominent in areas of the country where lakes and ponds are frozen throughout three winter.

Conversely, it is this winter season that represents one of the best selling opportunities — since it provides the opportunity to "pre-sell" aquatic weed control... making it possible for the professional applicator to book jobs in advance and plan ahead to the busy months. It also makes control easier, since aquatic weeds are best controlled during their early growth periods.

There is a strong trend in aquatic weed control toward greater professionalism. Fewer and fewer applicators are working job by job — but instead, are providing year-round complete aquatic vegetation control management on contract. Further, it remains one of the few rapidly growing markets in the agricultural and/or herbicidal chemical application market.

Many applicators already have on hand the necessary equipment to enter the chemical segment of aquatic weed control. Practically all of the aquatic chemicals come in liquid, granular or pellet formulations. The few powder formulations on the market are generally tank-mixed with other liquid formulations before application.

For the professional applicator, probably the most common equipment is the boat combination. Judging investment is still difficult because of the wide variation in boats, motors, pumps, etc. However, an estimate in round figures for a set-up that could handle most sizable jobs would include:

<table>
<thead>
<tr>
<th>Equipment</th>
<th>Approx. Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boat—16 ft.</td>
<td>$300.00</td>
</tr>
<tr>
<td>Motor—9.5 h.p.</td>
<td>$350.00</td>
</tr>
<tr>
<td>Trailer</td>
<td>$250.00</td>
</tr>
<tr>
<td>Pump and fittings</td>
<td>$250.00</td>
</tr>
<tr>
<td>Miscellaneous</td>
<td>$150.00</td>
</tr>
<tr>
<td>Safety goggles,</td>
<td></td>
</tr>
<tr>
<td>gloves, oars,</td>
<td></td>
</tr>
<tr>
<td>tools, etc.</td>
<td></td>
</tr>
<tr>
<td><strong>TOTAL</strong></td>
<td><strong>$1,300.00</strong></td>
</tr>
</tbody>
</table>

Obviously, these figures would vary throughout the country. They would also vary depending on the "newness" of the equipment and the amount of equipment already on-hand. And, finally, they would vary depending on the market intended.

(continued on page ZZ)
1974 will be a bad year for bugs.
Bad for bugs of turf and ornamental plants. And bad for household and structural bugs. Because Dow has a pair of insecticides that will make their lives miserable. There's ZECTRAN* insecticide, a general use biodegradable insect killer that works on almost all major foliage-feeding insect pests—even the hard-to-kill kinds. Use ZECTRAN on over 600 different flowers, ground covers, trees, shrubs and turf. And then there's DURSBAN* insecticide. Its effectiveness, economy, non-phytotoxicity and biodegradability make it the choice of professional turf men for golf greens, turf farms, home and
industrial lawns—or wherever grass and ornamentals are grown. It's especially effective
to control the hairy chinch bug and sod webworm. DURSBAN insecticide is also
preferred by PCO's for controlling household and structural pests—especially resistant
roaches that laugh at other sprays. Please remember to read and observe all precautions
on the product label. Bugs, get ready for 1974!

*Trademark of The Dow Chemical Company
Economics for controlling grassy and broad-leaf weeds in most fine turf. They don't look pretty. Economics also enters the picture.

Desirable grasses revert to a relatively dormant state during the hot summer months. Weeds don't. They flourish. The result is that weeds are about all that is mowed in non-irrigated turf during the hot months. One or two effective herbicide applications should save your customer money by eliminating additional mowing costs created by weeds.

Economics of another sort enters the golf course market. People generally prefer to play their game on a well-kept course. Weeds could send players to other courses, reducing revenues for the weedy course.

Tall weeds that dry out in late summer present a fire hazard and also do a good job of serving as hiding places for rats and other undesirable varmints. Weeds also produce pollens—a cause of allergies. Weedy vacant lots in cities create eyesores. So, as you can see, there are a number of good reasons for controlling weeds.

Another factor to consider is the application of herbicides in the fall. Traditionally, about 80 percent of the work usually has been done in the spring. This concentrates your activities into a relatively short period. This time span can be further reduced (and often is) by rain, which can make it impossible for application equipment to get onto the turf. This, in turn, can stretch your capabilities and prevent you from taking on new customers.

Today, however, there is a trend away from application solely in the spring. Many universities are recommending fall application of herbicides to control and prevent broad-leaf and grassy weeds from appearing next spring. This not only gives your business more flexibility but also gives you the opportunity to apply chemicals during the fall when weather conditions are usually more favorable. Chemical drift is less of a problem in the fall because most vegetables, flowers, and other annual plants have completed their growing cycles.

The fall also is the best time to seek new business. It's usually the time when those responsible for turf care are planning their budgets for the following year. Once a potential customer has committed money for the year, you probably will not be able to get any of his business. By contacting him early you have a good opportunity to work your program into his future plans.

AQUATIC WEEDS
(from page WW)

For example, if you intended to work exclusively in the golf-course segment of the industry, you might not need a boat at all—or a small skiff would easily suffice. At the other extreme, if your entire market were irrigation and flood canals, an air-powered hydroplane skimmer with booms or sunken drag hoses will probably be necessary.

Interestingly, it generally doesn't take a lot to pay off the initial investment and begin to recognize valid profits. Using the outfit above, lets take a typical example.

Generally, lakes are not treated across the entire surface. This is because aquatic weeds in deeper segments of the lake are not bothersome and/or simply do not get sufficient sunlight to grow. On a small 10 acre job along the shoreline of a lake, treatment would usually average out to about four feet deep. Thus, an applicator would be treating 40 acre feet.

The chemical to be used would vary depending on the treatment necessary and the type of aquatic weed to be controlled. In Michigan, for example, Aquathol Plus will usually do the job at 3 ppm (parts per million). Three ppm is equal to 66-1/2 gallons for the job. To make it easier to figure and provide a bit of a safety factor, lets use 70 gallons.

The chemical cost to the professional applicator for Aquathol Plus was $10.90 in 1973—or 763.00 for 70 gallons. Many applicators, on a job of this size, just double the chemical cost and charge the customer that amount. Others sell the chemical at the retail price and add on an application charge. The application fee may vary depending on the size, distance traveled, location and difficulty of the job.

For this job, let's use the second method. Seventy gallons at a retail price of $13.00/gallon equals $910.00. If an application fee of $10.00 per acre foot is used (total = $400); then the total bill to the customer equals $1,310.00. The applicator has a dollar profit of $547.00. As you can see, it does not take too much time to write-off an initial investment. The professional's key is balancing his investment to the potential market in his area; or to the market he seeks to penetrate.

Just exactly what is the job? Well, the first element is to identify the market or markets. Beyond that, there are essentially six steps.

1. Meet with your customer and discuss their particular needs. Does he want to fish, swim, boat or waterski—or is he an industrial requirement such as irrigation or flood control; or purely aesthetic. Different chemicals do different jobs.

2. Survey the area to be treated to obtain information concerning the aquatic vegetation, water quality and storage capacity. Identification of the specific water weeds and/or algae is paramount to successful control—and there are well over 25 different varieties (generally easily identifiable from state manuals or chemical supplier technical information sheets).

3. Select the proper materials to do the most effective job, consistent with state and federal environmental protection laws. I reemphasize the state laws because they vary widely from state to state even in similar geographical regions.

4. Offer your customer your contract and clearly outline what he will receive, and what payment schedule will be made. Some applicators provide "easy payment" schedules of 50% down and the remainder in 30 days—or in two payments of 30 and 60 days. Most year-round management contracts guarantee a specific performance or control ratio.

5. Apply the herbicide. Obviously, the length of time required to apply the herbicide varies widely with the type of application and the type of equipment. With boat or mechanical spreaders the average is probably between 5 and 10 acres per hour.

6. Inspect the treated area periodically to determine if adequate weed control has been achieved.

For the professional applicator, penetrating the aquatic weeds market may prove a very satisfactory and financially rewarding opportunity . . . or it may not be "your cup of tea."

At Pennwalt Corporation we have a large number of technical sales representatives that specialize in the aquatic weed control market. These people are experienced and helpful and willing to assist in the investigation of aquatic markets and business development.
We know Agrico Country Club Fertilizer can improve fairways. Because it feeds more efficiently to help build plusher turf—turf that will approach your greens in quality.

We'll prove it to you on your own course, free of charge.

Formulated with moderate-size granules, Agrico 18-5-9 can be spin-spread faster and more accurately. Once spread, 18-5-9's power-feeding formula makes your fairway turf uniformly thicker. This helps "keep the ball high on every lie" and gives your golfers better fairway shots.

And because 18-5-9 is high in nitrogen content, you need fewer bags for normal fertilization. A real savings when you've got 40 to 65 acres of fairways.

The nitrogen is derived from organic as well as quick green-up sources. Five units of nitrogen are in water insoluble form to keep your turf greener—longer.

Higher potash content, one-third from sulphate, makes turf so resilient that it resists tracking—even under heavy traffic conditions. Five units of phosphorus will maintain, but not increase soil levels.

"We'll Go To Any Links"
To prove that Agrico can improve your fairways, we'll go to any links. Complete the coupon below and we'll come to you with a free product demonstration. We'll prove beyond a doubt the effectiveness of Agrico's 18-5-9 formula for fairways. And we'll fill you in on Agrico's full line of dependable course-care products.

Agrico Country Club
P.O. Box 317
Lebanon, Pennsylvania 17042

Please contact me for a free product demonstration of 18-4-10 and 18-5-9 and for information on Agrico's other course-care products.

Offer good only in Agrico trade areas.
This entire area was seeded with bluegrass and crabgrass. The left-hand side was sprayed with Tupersan the same day it was seeded. Note crabgrass on the right (untreated area) and the absence of crabgrass in the treated area.

The same areas thirty days after seeding and treating. Tupersan made the difference. Note crabgrass growth in the untreated area at right and how Tupersan controlled crabgrass in the treated area at the left.

Tupersan® crabgrass killer
permits seeding & treating the same day

Du Pont Tupersan is a unique, highly selective, pre-emergence weed killer for the control of crabgrass (smooth and hairy) and certain other annual weed grasses in turf. Tupersan offers a high degree of safety to turf. It can be used on newly seeded areas without causing injury to germinating seeds of cool-season grasses. It can also be used safely on established turf.

You can seed and treat the same day with Tupersan. It prevents crabgrass—but lets the desirable grass grow. For full information on Tupersan, consult your golf course supplier—your service agency.

With any chemical, follow labeling instructions and warnings carefully.
