Do it right the first time
...especially if it's your second chance!

Whether it's a new installation or a retro-fit, your irrigation design is only as good as your controller. Input from landscape architects and contractors was invaluable in the development of the most advanced and reliable line of solid-state controllers in the industry...Irri-Trol's MC Series.

Consider these features:
- Proven reliability
- 4, 8, 12, 18, 24, 30 & 36-station models
- Simple & easy to program
- Memory protection from power failure provided by one 9 volt battery
- Automatically activated safety back-up program
- Bright digital display for daylight visibility
- Split-second accuracy
- Weatherproof steel case, UL approved for outdoor installation
- Pedestal mount available
- True dual programming
- Master valve or pump start station
- Individual station lights, indicating the actuated valve

Next Time, The Computerized Irrigation System!

ferent rates of the regulators and weighed them every 24 hours. He found growth regulators can save 20 to 30 percent in water use. Results from studies with bermudagrass were not as significant.

Salt tolerance
At the A&M research center in El Paso, TX, Dr. Garald Horst is evaluating zoysias, St. Augustine and bermudas for salt tolerance and water use rates. He expects the research to go on for another two years. Bluegrass, tall fescues and ryegrasses have been completed.

Horst conducts his salinity tests with grasses bred by Dr. Milt Engelke at the Texas Agricultural Experiment Station, Dallas.

"We have come up with some good germ plasms for salt tolerance, but the tests need some refinement and then we will test again. Horst analyzes 20 cultivars of each variety.

Ninety percent of Horst's work is oriented toward urban use.

"I think education and public awareness is the way to go," Horst maintains. "Lots can be changed by just altering people's water habits."

Horst also sits on the El Paso Park Board which oversees 630 acres of park land, and made a presentation to the board on water conserving grass.

"People are amazed that you can use less water and less fertilizer and still have the same quality grass."

University of Florida
Quantity of water isn't the problem in Florida, which averages 50 to 60 inches of rain a year. Quality is a problem. Because the soil is sand, there is a constant threat of chemicals leaching into the groundwater supply.

Still, Dr. Bruce Augustin of the University of Florida Institute of Food and Agricultural Sciences, Ft. Lauderdale, is trying to find ways of drought conditioning turf. He is studying nitrogen and potassium by taking recommended rates and going lower under different irrigation levels which include: daily (the type the typical homeowner would use) evapotranspiration replacement (twice a week or best "guessimate" of when to water); and wilt only (irrigates only when 30 to 50 percent of the turf plot is wilting.)

"The thrust of my work is on visual tests and common sense," says Augustin.

His testing has found that irrigation can be limited to an as-needed basis instead of sticking to a set schedule (which could cause over-irrigation) and produce better results. Also, water soluble nitrogen can be used as effectively as slow-release nitrogen with the added benefit of being less expensive.

Another problem in South Florida is the chemical content of the soil.

"We have some phosphorous but it doesn't move in the soil," said Augustin. "Nitrogen and potassium have to be added on a regular basis."

Augustin uses a Troxler density gauge for measuring moisture in the soil.

"I've found that homeowners and superintendents can tell how many minutes they've watered but not how many inches," explained Augustin.

"In water conservation, the latter is more important."

University of Nebraska
Dr. Robert Shearman at the University of Nebraska is trying to determine evapotranspiration rates for cool season turfgrass species and cultivars and is looking at drought avoidance mechanisms in the same grasses which include tall fescue, Kentucky bluegrass, fine-leaved fescues, perennial ryegrasses, creeping bentgrasses and annual bluegrass.

He has overseen the work being done at Nebraska, another large uni-

Rain Bird has the finest irrigation products in the world. And they are keeping thousands and thousands of golf courses green.

Why not join this prestigious list of Rain Bird courses?
GET YOUR CREWS OUT OF THE ROUGH IN ONE SHOT WITH ROUNDUP.

You want your crews to spend most of their time tending fairways, greens and other showcase areas—rather than in the rough fighting poison ivy and other nuisance weeds. That's why so many groundkeepers use Roundup® herbicide for weed control.

One-shot Roundup controls weeds, roots and all, so they won't grow back—over 100 species, including poison ivy, poison oak, kudzu and brush.

Roundup is not only effective—it's economical. One gallon of a 2% spray solution can treat up to 1,000 feet of fenceline for less than $2.00, or the area around 30 trees for about a nickel apiece.

And just one application can replace as many as 6 string trimmings throughout a season.

Because Roundup won't wash, leach or carryover in the soil, you can use it around trees, shrubs and expensive ornamentals. And it's virtually odorless and environmentally sound. That's a nice plus in heavily trafficked areas.

Get your ground crews back on course—and out of the rough with Roundup.

*Based on cost of Roundup alone treating low growing vegetation.

University of California, Riverside

Editor's note: Much of the low water use turf research in California has been done by Drs. Victor Youngner and Victor Gibeault. Two weeks after WEEDS TREES & TURF interviewed Dr. Youngner for this story, he died of a heart attack. Because of the timing of his comments and the commitment Dr. Youngner showed to this industry over the past 30 years, his comments have remained in the story.

In 1986, Dr. Victor Youngner of the University of California, Riverside, released a bermudagrass cultivar he developed called Santa Ana. At the time it was hailed for its tolerance to smog and ability to continue growth right into the cool winter season. The fact that it was a water efficient grass was noted, but at the time, smog was a bigger danger than water consumption.

That has changed. It was in the 70's that Youngner began his research with the now retired Dr. Al Marsh, to determine the water requirements of turfgrasses. They chose two warm season grasses—St. Augustine and common bermuda and two cool season—Alta tall fescue and Merion Kentucky bluegrass. The two consecutive studies were done over several years. The study found warm season grasses to use much less water with virtually no effect on turf quality. Fescues also did well. Bluegrasses were stressed. The Youngner/Marsh test was the first time this data was produced.

This year, another Youngner zoysia cultivar will be released called El Toro. This is another turf with low water requirements.

Ongoing research, supported by the Metropolitan Water District, is looking at the survival ability of several grass species under severely reduced water levels. They include three warm season grasses (Santa Ana bermudagrass, paspalum vaginatum (Adalayd and Excalibur) and Jade zoysia) and three cool season (a blend of several bluegrasses, a blend of several ryegrasses and Alta tall fescue.)

Wetting agents

Studies done by Dr. John Letty, also of the Riverside campus, on wetting agents, concluded that when soils repel water for whatever reason, (organics, thatch build-up, etc.) surfactants have been found to allow better water penetration.

Youngner agreed. "Wetting agents are of use in water conservation to avoid runoff in areas with hydrophobic soils or thatch," he said.

Alternatives

Youngner's colleague, Dr. Vic Gibeault, an environmental horticulturist with the University of California Agricultural Extension, Riverside, is focusing his current work on studying alternative plant materials that would use less water than turf.

The facts tend to support this research.

In Southern California, where 60 percent of the state's population lives, 3.1 million acre feet of water is used by 12.1 million people. That figure can rise to as much as 3.6 acre feet. With the loss, however, of part of its Colorado River supply in a few years because of a water rights dispute. Gibeault explained that that would put the Southern California water supply right on line—no surplus.

"Because we would not be dealing with a surplus situation, restrictions could be placed on the water supply at any time."

There is also an estimated influx of 3 million people coming into the state in the next 16 years; a whopping 25 percent population increase.

"We started looking at turf usage and came up with 1.4 million acres of turf in California," Gibeault said. "Of those acres, 65 to 70 percent are residential and 35 percent are professionally maintained such as golf courses, parks, cemeteries and military bases. Lots of water is being used to irrigate turf."

"About five years ago, we started water awareness programs with those in the professional turf community. Our goal is to paint a long-term scenario. The professional industry is recognizing the problem very clearly. Some facilities have changed from cool to warm season grasses because of their water-saving qualities. Homeowner awareness is a great problem."

Gibeault also explained there's some hesitancy among golf course superintendents because of the dormancy of warm season grasses. Much of the zoysia work at the U of C, Riverside, is aimed at finding cultures with less dormancy to make the grass more appealing and acceptable aesthetically.

In the 1.4 million acres of turf in Southern California, within each area, such as golf courses and parks, if water use areas were identified, you'd come up with about 50 percent of the area in existing grasses. Gibeault maintains these areas don't "need" to be planted in grass.

"We plan on studying alternatives that use less water and are just as pleasing to look at," he said.

Gibeault feels there's an issue that even overrides the type of turf selected in areas where water is precious—and that's irrigation equipment design.

"We always have to deal with the driest spot. If a system isn't designed well it wastes a great deal of water. Up until now, water has been too cheap to go with a more expensive system. In most cases, we're using twice as much water as we really need."

Major irrigation companies in the U.S. couldn't agree more.
When there's a lot on the line, professionals choose TORO!

That's why TORO was a key performer at Munich, Montreal and Los Angeles

Stadiums that hosted three of the last four Olympic Games chose Toro 640 sprinkler heads for the vital task of irrigation when the eyes of the world were focused on their turf. No wonder! Toro 640s are safe, with a very small 2\(\frac{1}{4}\)-inch exposed surface. And they install 1\(\frac{1}{2}\)-inch below grade. They pop up 2\(\frac{3}{8}\)" for efficient watering, then fully retract with heavy duty stainless steel springs. To top it all, these superior sprinklers are backed by Toro's 7-year warranty. Oh, about the fourth Olympic site, Moscow? Well, we really don't know, but we'd be willing to bet that the Russians wish they had invented the Toro 640! Toro, the leader in sports field and large turf irrigation products.

Irrigation: putting water where it’s needed when it’s needed

One area where water conservation awareness is a top priority is in irrigation equipment manufacturing companies.

The overriding concern is convincing people that a professionally-installed irrigation system is one of the best and most efficient ways to put water where it’s needed and only when it’s needed.

Ninety percent of all irrigation companies in the country are located in California; that includes three of the largest, Toro, Buckner, and Rain Bird. Located in a Dallas, TX, suburb is another, Weathermatic.

Rainbird

Rainbird’s Mike Baron is product development manager and says the company’s philosophy is to make its products more efficient.

“Water conservation is very important to us,” says Baron. “We don’t want to wait until government mandates come down before we start confronting the problem. We (irrigation industry) will probably be targeted first (for any type of restrictions).”

Baron said there are two schools of thought—one is ‘I’m going to water less but stay wasteful’ and the other, ‘I’m going to water more efficiently and make it do more.’ The latter is what Rain Bird and other irrigation companies espouse.

“What it boils down to is the selection of equipment designed so as to avoid waste and the proper installation and maintenance.”

—Putnam

Baron also believes the manufacturer must play a role in educating landscapers and contractors in the latest in equipment and in the type of equipment that would best suit their needs and those of conservation.

“In 1982, we developed a pressure compensating bubbler installed on a fixed riser,” said Baron. “We determined the reason why it hadn’t taken off faster with contractors was because it was new, installation was different and they were wary of it.”

From January through April, the characteristically slow season for irrigation contractors, Rain Bird provides distributors and managers with slides and notebooks to educate their contractors on the latest methods and equipment.

The reception to the pressure compensating bubbler has improved considerably.

“Pressure regulation is the key because it allows transition from the design to whatever the contractor has planned for it. This type of bubbler is able to balance the precise amount of water coming out.”

Baron pointed out the controlling system is also important.

“With the new solid state designs, you can be more precise with when you want to water than with mechanical dials. The slight fluctuations (in mis-timed controllers) do add up.”
Rain Bird was the first irrigation manufacturer to have matched precipitation rates across nozzle sets, which means the amount of water going onto an area is the same regardless of the trajectory pattern.

The Toro Company was the first to introduce matched precipitation rates, but Rain Bird was the first to match it across sets—saving designers time and money, according to Baron.

**Toro**

John Skidgel, golf marketing manager of Toro Irrigation, Riverside, CA, agrees the secret to efficient irrigation is in the controller, and at press time, the company was scheduled to introduce a new one.

"The future of the industry is computerization," predicts Skidgel. "We already have gotten away from drawing boards and use computer-aided design for our systems. The future of our business is meeting the needs of different groups and doing it with conservation in mind and still maintain a nice-looking turf."

**Buckner**

At Buckner Sprinklers in Fresno, CA, energy conservation is as highly regarded as water conservation in the company's irrigation systems.

Sprinklers and valves requiring less pressure require less horsepower and therefore less electricity.

The company, according to golf marketing manager David Truttmann, is also incorporating in its system design, a reduced angle of trajectory so that water gets to the soil faster and that there is less of chance for the wind to carry off water spray.

Buckner's controllers have their own video control system which permits watering only when necessary.

They are also teaching designers and users about the equipment and what equipment works best in various situations.

"Energy and water conservation have always been a concern to the ag industry, but only recently have they become important to turf," commented Truttmann.

**Weather-matic**

Charles Putnam is vice president of sales for Telsco Weather-matic, Garland, TX, and is incoming president of the Irrigation Association. He worries about the industry "over technologying" itself.

"We need to educate the public to put water where it's needed," says Putnam. "Even if it's inexpensive, an automatic system is better because it's more efficient."

Seventy-five percent of the company's business is in the commercial market and Putnam says business is great.

Weather-matic fully supports an irrigation licensing law that went into effect in 1973 and is the most advanced law of its kind in the country.

The Texas Board of Landscape Irrigators was one of the driving forces behind it.

"Basically, it protects the consumer and protects the supply of potable water," Putnam explained.

Of the 900 would-be irrigation contractors who take the test, only about half of them pass. The test includes designing an irrigation system with water conservation in mind.

Putnam outlined the company's philosophy on water conservation.

"What it boils down to is the selection of equipment, designed so as to avoid waste, and the proper installation and maintenance."

Putnam also believes that down the road controllers will become obsolete.

"Systems will be developed that waters only when the ground needs it," he said.

The company's Rain-stat comes close to that. The device overrides the controller so that when it gets to a certain level of rainwater, it turns the system off.

"In the future we'll see more input from landscape architects and local codes. These are the things that will dictate water usage. There'll be much greater municipality control," Putnam concluded.

**Drip irrigation**

Drip irrigation, (water comes out precisely where the emitter is with no spray) while prevalent in the agricultural industry, is not as popular in the landscaping profession.

Skidgel from Toro says that most landscape areas are well-trafficked and that having drip emitters in those areas would not be practical. Toro, does, however, market a brand so its distributors will have it to offer customers.

"It (drip irrigation in landscaping) is a coming thing, no doubt," Skidgel said.

Rain Bird is making clear its position in the drip market. Says Baron, "We have a line of drip irrigators and some lines under development. We want to be in the forefront of products using localized irrigation."

Weather-matic's Putnam is more pragmatic.

"An increase in water rates will increase interest."

---

**Four Books Superintendents**

**Turf Management for Golf Courses**

by James B. Beard

Beard's Turfgrass Science and Culture is the leading basic textbook for turf. In his new book, Beard devotes his attention specifically to golf turf, both cool-season and warm-season. The result is perhaps the single, most important book a golf course superintendent can own.

Beard begins with the history of golf, proceeds to course construction, devotes the majority of the book to book to maintenance, and then completes the reference with information on management, tournament preparation, buildings, and more. 648 pages, $45

**The Golf Course**

by Geoffrey Cornish and Ron Whitten

Much of maintaining a golf course is understanding why the course was built the way it was. This beautifully illustrated book presents the history of golf courses and golf course architecture.

The introduction by Robert Trent Jones says the book financially gives credit to those who were responsible for innovations in the game and the design of courses. One of the highlights of the book is a course by course list of golf course architects and designers and their background.

As a superintendent, you might ask why you need a book about architects. After reading this book and enjoying its photos of historic courses, you will understand why. 320 pages, $35

**Turf Irrigation Manual**

by James Watkins

Next to the land and buildings, the irrigation system is the most valuable asset of a golf course. It only makes sense to have a strong reference to help you maintain and repair this expensive and complicated system.

Watkins, with more than 40 years of experience in irrigation design and operation, wrote this book as both an educational tool and a problem solver for irrigation designers and contractors. After reading this book, you'll know as much about irrigation as the people who put your system in. 360 pages, $22.95

**Management of Turfgrass Diseases**

by J. M. Vargas

Diseases are perhaps the most complicated pests superintendents have to deal with regularly. Vargas has made great effort to simplify and clarify turf diseases and their control.

In addition to simplified explanation of cool- and warm-season turf diseases, Vargas devotes 36 pages specifically to managing turf diseases on golf courses.

Vargas covers all factors of turf disease, including soil, turfgrass varieties, irrigation, drainage, mowing and other pesticides. Get a step ahead of diseases by learning more about them before they occur, you'll need a reference that explains the solution simply and clearly. 208 pages, $24.95

To order, send cost of book(s), along with $3.00 postage and handling plus $1.00 for each additional book to: Book Sales, HBJ Publications, One East First Street, Duluth, MN 55802. Please allow 6-8 weeks for delivery.
The United States Golf Association Green Section is the leader in low water use, minimal maintenance turfgrass research funding. This year alone, it has made a $332,000 commitment for research and a $3 to $4 million commitment within the next eight to 10 years.

National Director William Bengeyfield says research has become one of the Association's main goals.

"We have formed a Turfgrass Research Advisory Committee to direct a long-range program to develop minimal maintenance turf for golf," explained Bengeyfield. "Lower water use, use of effluent for irrigation and breeding are all included." All of the projects are long-range, especially the breeding program which is a 10 to 20 year project.

The nine member Advisory Committee, made up of researchers, association personnel and others involved in golf, meets four or five times a year to discuss progress, problems and other related matters.

Besides funding individuals at various universities across the country, the USGA has brought together a computer data base research library at Michigan State. Under the direction of Dr. Richard Chapen, director of libraries at MSU, the library is attempting to bring together all available information on turf research ever printed.

"Eventually the library will be developed so that extension personnel and superintendents can tap into the library for all the latest information," says Bengeyfield.

Bengeyfield credits former National Director Al Radko with conceiving and implementing the original project.

"It was really Al's vision from the beginning."

American Society of Golf Course Architects

Dr. Michael J. Hurdzan, president of the American Society of Golf Course Architects and a partner in Kidwell & Hurdzan, Inc., Columbus, OH, is very aware that people are looking to his profession to find many golf course-related water saving answers.

"Although golf courses appear to use a lot of water, they don't really because of the area they cover," explains Hurdzan. "Because of the evapotranspiration rate, courses can lose up to 1/4 inch of water a day."

Hurdzan estimates an average 18-hole course can use up to a million and a half to two million gallons per week to irrigate tees, greens and fairways, depending on the weather of the area.

"There are ways to conserve on greens which are the highest water-use areas," he says. "How the substructure of the green is created makes a difference." The three substructures Hurdzan referred to are the Purr-Wick (P.A.T.) system, the USGA method and the Modified Greens Construction method.

Selection of cultivars can be another area of water savings.

At Dennis Highlands, a course in Cape Cod, MA, that Hurdzan's firm is working on, he was confronted with high, sandy soil, water from an underground aquifer and a community very aware and concerned about groundwater pollution.

Hurdzan used a seed mix of low nitrogen hard fescue and chewings fescue for the rough, since after the first year, almost no nitrogen would be needed and that would lessen nitrogen-A brush burial site is planted with wild flowers near Hole No. 16 at Dennis Highlands golf course on Cape Cod. Golf course architect Michael Hurdzan used flowers to reduce maintenance, lower water consumption reduced mowing and minimum fertilization requirements.
