# **Michigan Corn Production**

## **HYBRIDS COMPARED**

### **1988**

**BY: E.C. Rossman, Keith Dysinger,  
Mervin Chamberlain, and R.H. Leep**

**Authors are, respectively, Professor,  
Research Technician, Research Aide,  
and Associate Professor, Crop and  
Soil Sciences Department.**

**2**

**H**ybrid corn trials are conducted each year by the Michigan Agricultural Experiment Station in cooperation with the Cooperative Extension Service, seed corn companies and farmers.

Many different hybrids are offered for sale in Michigan. They differ in yield ability, maturity, lodging resistance and other characteristics. Choosing the best corn hybrids is an important part of profitable corn production. By planting the best hybrids, farmers can obtain higher yields and other improvements with little or no increase in production costs. Seed of the best hybrids generally costs no more than seed of hybrids with lower performance.

The highest yielding hybrids in the 1987 trials produced 30 bushels more corn per acre than the average of the 358 hybrids tested (Table A) and 62 bushels more than the lowest yielding hybrids. At 18 testing locations, the yields were 158 bushels for the highest, 128 bushels for the average and 96 bushels for the lowest yielding hybrids. The driest hybrids at harvest contained 8 percent less moisture than the wettest hybrids tested. Stalk breakage averaged 11 percent for hybrids with the highest amount of stalk lodging, 4 percent for the average and 0.3 percent for the lowest.

#### **Entries**

All seed companies are invited to enter hybrids in the trials each year. A fee is charged to cover some of the direct expenses.

Table 25 presents an index of all hybrids entered in the 1987 trials. At the 18 locations, 358 hybrids were tested as 1,915 entries. Company names used in association with hybrid numbers refer to the brand. The number is the hybrid designation. Single-cross hybrids are indicated with (2X), three-way hybrids with (3X), double-cross hybrids with (4X), modified single-cross hybrids with (MSX) and special cross hybrids with (Sp) following the hybrid name and number in the index (Table 25).

#### **Methods**

Scientific methods are used to conduct these trials to give all hybrids equal opportunity to demonstrate their capabilities. The best way to compare a group of corn hybrids is to grow them all in the same field with the same fertilizer, population, date of planting, etc.

Seed companies submitted seed for all entries. Equal numbers of seeds were counted for each plot of all hybrids. Each hybrid was replicated several times in the field. Plots were planted with a standard, two-row corn planter adapted for small plots.

From seed packaging through harvest and data processing, each hybrid was identified only by a code number to reduce the chance of biased results. The code was deciphered after the data had been processed.

Stands and lodging were counted before harvest. Plots were harvested mechanically for both grain and silage yields.

Silage yields were taken on all hybrids in trials of Ingham, Sanilac, Huron, Missaukee, Alpena, and Alger counties (Tables 10, 12, 15, 20, 22 and 24).

Irrigated and non-irrigated comparisons were made in the Montcalm County trial (Table 17). There were two locations in Cass County—upland soil with irrigation (Table 5) and muck soil (Table 6). The trial in Hillsdale County (Table 2) was also irrigated.

The two trials in the Upper Peninsula, Menominee and Alger counties, were failures due to deer damage and poor stands. Tables 23 and 24 present 1986, 1985 and 1984 data for these two locations.

#### **Growing Conditions**

All planting was completed between April 25 and May 27. Planting was timely and ahead of normal at most locations. The growing season was warmer than normal and corn grew rapidly.

Plant height averaged 45 inches by July 5

compared to 26 last year and 25 for the 5-year average, and some tasseling was reported. During the next two weeks, average height increased to 67 inches compared to 53 last year and 48 for the 5-year average. Eighty-five percent of the crop was silked by July 26 compared to 55 percent in 1986 and 45 percent for the 5-year average.

Temperatures in the 90's and below normal rainfall during the last half of July and the first half of August reduced yields at several locations, notably Kalamazoo and Huron county trials.

Corn matured rapidly. Seventy-five percent was denting by August 30. This compared to 20 percent in 1986 and for the 5-year average. Practically all corn matured before any killing frost occurred.

Moisture content of grain at harvest was much lower than average for Michigan. Quality of grain was excellent with high test weight.

Total corn acreage was 2,300,000, down 18% from 1986 and 25% less than 1985. The Michigan Crop Reporting Service estimates a state average yield of 95 bushels per acre in 1987 on 1,950,000 acres harvested for grain. Total production is estimated at 185,250,000 bushels, 28 percent less than 1986. State average yields were 105 in 1986 and 1985, 84 in 1984, 92 in 1983 and 107 (highest on record) in 1982.

## How To Use This Bulletin

One-, two- and three-year averages are presented for all hybrids tested during 1987, 1986 and 1985. One-year data are less reliable than two- or three-year averages and should be interpreted with more caution. Confidence in corn performance data increases with the number of years and locations of testing. Two years' results, or more, are more desirable than one year's.

The tables show the following about the hybrids tested:

1. Average moisture content at harvest.
2. Average yield (in bushels) of shelled corn at 15.5 percent moisture.
3. Average percent of stalk lodging (plants broken below the ear at harvest).

Hybrids are recorded in the tables in order of their approximate maturity (early to late) based on moisture content at harvest.

Moisture content was determined from shelled grain samples at all locations harvested for grain and from chopped silage (fodder plus grain) in the silage trials.

Stalk breakage is caused by corn borers and/or stalk rot diseases.

Two or more plots of the same hybrid in the same field may produce somewhat different results due to uncontrolled variability in the soil and other environmental factors. Replication and randomization of the entries are two methods used to reduce these errors. Since these methods do not eliminate all of these variables, differences necessary for statistical significance have been calculated for yield and moisture content.

When comparing any two hybrids, the difference between them should not be considered significant unless it exceeds the value listed as "least significant difference" at the bottom of the tables.

Hybrids with yields significantly better than the average grain yield at each location are marked with an asterisk (\*) in each table. The least significant difference for yield was added to the average yield. Hybrids exceeding this yield are starred. There are some statistically significant differences among hybrids significantly better than average yield in 1987.

Agronomic information for each trial is given at the bottom of each table. Fertilizer amounts are total pounds per acre of nitrogen, P<sub>2</sub>O<sub>5</sub> and K<sub>2</sub>O applied during the season.

## How to Choose a Hybrid

### Adaptation

The following map shows the location of the trials and divides Michigan into four maturity zones, but only in a general way. Local variations in weather, soil type and fertility, time of planting and other conditions all affect adaptation. Corn hybrids are often adapted to

more than one zone.

Find the zone in which you plan to grow the corn, and refer to the table that gives results for the trials conducted nearest you. Also, refer to the other tables listed in your zone. A hybrid that has done well at two or more locations is more likely to be a good hybrid for your farm, too.

Corn Maturity Zones and Locations (\*) of Trials

### Planting Rate

High plant populations (20,000 or more per acre) should be considered only for soils consistently producing more than 100 bushels per acre. Rainfall deficiencies with high plant populations usually result in no increase in yield and frequently a decrease, compared to 18,000 to 19,000 plants per acre. Lodging and harvest losses are often greater at higher populations.

### Maturity

Hybrids are listed in the tables in order of

maturity (early to late) based on moisture content of the grain at harvest. This is usually a reasonable, accurate measure of relative maturity in most years in Michigan. Early-maturing hybrids are generally lower in moisture content than later-maturing hybrids. Differences among hybrids in rate of drying in the field also affect moisture content at harvest, but usually do not greatly disturb the relative maturity ratings as determined by moisture content.

One percent more moisture at harvest means a delay in maturity of about two days. Corn is mature when moisture is about 32 percent in the grain or 38 percent in the ear.

## For Grain

It is better to choose an early corn (below average moisture content) than a late corn for grain. The tables show that good yields do not depend on later maturity. Advantages of early-maturing hybrids are:

- They usually mature before killing frosts.
- Good-yielding early hybrids generally yield as much or more than late hybrids in most areas of Michigan.
- Early hybrids with lower moisture content at harvest reduce drying costs and market discounts for moisture.
- Mature, dry corn makes better livestock feed.
- You can harvest earlier in the fall when weather conditions are most favorable. Early harvest may reduce corn losses resulting from broken stalks and dropped ears.
- Fall plowing of corn stubble may be possible with early hybrids on land not subject to erosion.

## For Silage

The best silage contains a high percentage of grain. Hybrids that produce high yields of grain should be used for silage. High dry-weight production per acre is a better reason for choosing hybrids for silage than tons of green weight.

Corn for silage should reach the early dent stage well before frost in an average year. The early dent stage, when most of the kernels have dented, is the best time to begin harvest for silage. Dry matter production continues to increase until maturity.

## Other Considerations

Choose early hybrids for late plantings, low soil fertility, sandy soils, muck soils and for corn that is to be followed by a winter grain or cover crop.

You can obtain some degree of "crop insurance" by choosing two or three hybrids that differ slightly in their maturity. If one hybrid runs into unfavorable weather at a critical stage of growth, another may be less affected and produce a good crop.

Even though you have been growing a hybrid that has given good results, you may be able to improve your corn by trying one or more hybrids with better records in these trials. Well-tested, new hybrids are worth trying. You may want to try a new hybrid in a strip in the same field with your present hybrid.

## Ways to Reduce Stalk Lodging

Several stalk-rotting fungi may cause broken stalks at harvest and create a major problem in corn production. Stalk rot occurs when fungi increase rapidly after the plant has matured or when the plant has died prematurely. Highest incidence of stalk rot occurs in years when corn matures early and when harvest is delayed. Infection and disease development are favored by warm, humid weather and abundant rainfall during the latter part of the growing season.

Hybrid resistance to stalk rot is only one of several factors that determine the extent of stalk breakage. There are no clear-cut cases of specific hybrids that can be depended upon consistently to resist stalk rot under all conditions of soil fertility, plant population, plant stress and maturity. A major part of the difference in resistance to lodging appears to be mechanical—stiffer stalks

do not break as soon when disease attacks.

The most effective practice to reduce losses from stalk rot is to harvest as soon as possible after maturity. Stalk breakage continues to increase rapidly in warm, damp weather when harvest is delayed. Early-maturing hybrids that mature in September will have more stalk breakage than late-maturing hybrids harvested in November and December. There may be little or no advantage to planting early-maturing hybrids if harvest is delayed.

To avoid problems, choose high-yielding, early-maturing hybrids, plant early and harvest early.

## Ways to Avoid Moldy Corn in 1988

Use the following recommendations to help prevent moldy corn in 1988.

- Plant early.
- Plant early to medium-early maturing hybrids.
- Harvest early—during October. Weather problems and harvest losses increase with later harvest.
- Plan for adequate artificial drying. Drying in the field and in the crib is slow and undependable in Michigan. Ready access to drying facilities will permit more timely harvest, prevent high harvest loss and produce greater corn profits.

## Seed Supplies for 1988

Production of hybrid seed corn in 1987 was good to very good. Seed supplies of most hybrids should be adequate for 1988 planting.

TABLE 25

Index for 358 hybrids entered as 1,915 entries in the 1987 Michigan Corn Performance Trials. Numbers within parentheses refer to table numbers in which the hybrid appears. (2X) indicates a single-cross hybrid, (MSX) indicates a modified single-cross, (3X) indicates a three-way hybrid, (4X) indicates a double-cross hybrid and (Sp.) indicates a special-cross hybrid. Company names used in association with hybrid numbers refer to the brand and the numbers are the variety (hybrid) designation.
