# Economics of Peach Production in Southwestern Michigan

Extension Bulletin E-1016

Revised June 1979

by Myron Kelsey and Archie Johnson<sup>1</sup>

THIS COST EVALUATION of peach production in southwest Michigan is a projection of costs developed from a small group discussion with peach growers. Growers described common growing and harvesting practices and prices paid for inputs used by average peach growers of the area. They agreed upon the size of peach acreage, equipment and cultural practices generally used by an average peach grower.

It should be stressed that these figures do not reflect the average cost of peach production for all growers in the area because higher than average yields have been assumed. You should not assume the figures reflect your cost of production because costs vary considerably from farm to farm.

The data can help you develop costs and better evaluate your farm situation. Each of the appropriate tables in this report includes a "Your Farm Cost" column for you to note your own cost for particular operations for the total peach enterprise. For operations where your costs cannot be determined, you may wish to adjust and substitute the study data.

The data were assembled assuming equipment and labor available for a hypothetical farm of 80 acres of diversified tree fruit, including 20 acres of peaches. However, the data are presented for 10 acres of peaches since it may be easier for a grower to visualize many of the resource inputs on this basis. Per acre costs can be determined by dividing by 10.

The full time labor classification includes the working time of the operator and regular hired help devoted to peaches. Operator labor is not considered a cash expense by producers, but to allow for differences in the proportion of work performed by regular hired help, which is a cash expense, or the operator, both have been included at the \$4.27 per hour rate. As a result, producers who do a major portion of the work may have a lower cash labor cost than the figures indicate. This rate is a base rate of \$3.50 per hour plus Social Security at 6.13% and Workers Compensation insurance at the proposed rate of 16%. Hourly labor was paid the minimum wage of \$2.90 per hour which equals \$3.54 with Social Security and Workers Compensation.

Some major factors considered in the computation of equipment costs are initial cost, salvage value, years of life, annual usage, repair costs, insurance, interest, and

operating expenses such as gas and oil. The operating costs for each item of equipment are charged to the crop in Table 1 on the basis of direct use of the equipment.

Variable costs are those that change directly with increases or decreases in the acreage or yield of peaches. Examples of such costs are spray material, fertilizer, hired labor, and machinery operating costs.

Fixed costs are those that do not change as the acreage or yield of peaches within the farm unit is increased or decreased. Such costs include taxes, interest on investment, and machinery depreciation. Total variable and fixed costs are shown as total growing, harvesting and overhead costs in Table 2.

Variable costs incurred in peach production are categorized by labor, machinery and materials in Table 3. Details of hours and type of labor, machinery used and hours of use, and kinds and amounts of material used by operation are shown in Table 1. If an individual grower's costs for particular items are substantially higher than those shown, he may need to closely analyze those components to see if they can be reduced. A high cost for a particular component may be justified if it contributes to a sufficiently higher yield or improved quality.

The variable costs incurred in the harvesting of 10 acres with estimated total production of 1,750 bushels of peaches are shown in Table 4. Labor is the major cost. Therefore, good labor management will enhance the profit picture. In *most* cases, there will be some economies or diseconomies for *some* cost items associated with higher or lower yields.

The fixed cost for peach production (Table 5) includes allocation of machinery overhead on the basis of the proportion of total farm use in peaches, interest on orchard investment and orchard depreciation, and taxes. The fixed costs of machinery are allocated to peaches on the basis of hours of use on peaches relative to the total hours of use of the equipment on the farm. Fixed costs on machinery include depreciation, interest on investment, insurance and housing costs (investment, insurance and housing equal 9.7 percent). Orchard

overhead includes orchard-depreciation, interest on investment in the orchard and land, and taxes.

You should evaluate your own situation and decide whether fixed costs should be considered as part of the total cost for decision-making purposes. Orchard overhead is a fixed cost to the owner, but a variable cost for the operator, if rented.

Average yields per acre obtained are very important factors in determining production costs per bushel of peaches (Table 6). These figures are based on the assumption that preharvest costs per acre, such as spraying, pruning, cultivation, etc., do not vary greatly regardless of the yield obtained.
