1983 MICHIGAN SOYBEAN PERFORMANCE REPORT

Extension Bulletin E-1206, January 1984

by J. J. Kells, T. G. Isleib, R. Leep, and D. E. Wolfe
Crop and Soil Sciences Dept.

This bulletin provides information on the performance of soybean varieties available in Michigan.

Comprehensive variety yield trials were conducted in Southeastern Michigan (Monroe County), Southwestern Michigan (St. Joseph County), and East Central Michigan (Sanilac County). Smaller trials were conducted in Huron and Delta Counties.

Testing Procedures

Commercial varieties were obtained from seed companies. No attempt was made to include commercial varieties not voluntarily entered in the 1983 trials. Public varieties were supplied by the Michigan Foundation Seed Association. Table 10 provides the names and locations of the companies and entries included in the trials.

Extension and farm cooperators, planting and harvest dates, fertilizer practices, previous crops, and soil management groups at the five locations are listed in Table 1.

Varieties entered in the early-to-medium maturity trials are considered maturity group I and varieties entered in the medium-to-late maturity trials are considered maturity group II, unless otherwise noted in the table. Entries were planted in plots 26 feet long and four rows wide, with a 20-inch row spacing. The planting rate was 4.5 seeds per foot of row and seeds were planted 1½" deep. Each plot was randomized in the field and replicated 3 times. Twelve feet of the center two rows were harvested for yield determinations.

Evaluation of Characteristics

YIELD — Yield is expressed in bushels per acre at 13% moisture.

MATURITY DATE — Entries were considered mature when 95% of the pods were a mature pod color and would crack under finger pressure. Additional

field drying was required before the plants were ready to harvest. Dates were recorded by month and day.

HEIGHT — Plant height, in inches, was measured at maturity from the soil surface to the tip of the main stem.

SEED SIZE — The number of seeds per pound was determined as a measure of seed size. The determination was made on clean, unsized seed.

LODGING — Lodging rates reflect the erectness of

Soybean Maturity Zones for Full-Season Varieties in Michigan, and Locations (*) of Trials.

the plants before harvest. Ratings are based on the following scale:

1. Almost all plants erect
2. All plants leaning slightly, or less than 25% of the plants down
3. All plants leaning moderately (45°), or 25% to 50% of the plants down
4. All plants leaning considerably, or 50% to 80% of the plants down
5. Almost all plants down

Results

Tables 2 through 9 show results of 1983 soybean variety trials. Values given are the averages of all replications harvested at each location.

Growing conditions varied between locations. In St. Joseph County, very dry growing conditions in late summer generally depressed yields. The Monroe County trial received more favorable rainfall patterns during the growing season and soybean yields were generally good. The location which had the highest yields in 1983 was in Sanilac County. This location produced very high soybean yields despite some minor injury from Banvel in mid-summer. A new location in Huron County, a field with no soybean history, was established in 1983. Soybeans at this location were treated with an in-furrow granular soybean inoculant to insure adequate nodulation. In the Saginaw County trial, poor soybean emergence resulted in generally depressed yields and high variability between replications. Since these results are unrepresentative of soybean yield performance in Saginaw County, they are not included in this report.

LSD values are given at the bottom of each table. The LSD (least significant difference) value is useful when comparing two varieties in the same table. Two varieties with the same genetic potential for yield may have different yields due to slight differences in soil fertility, compaction, and other environmental factors. If the difference between two varieties is less than the LSD value, the difference between the varieties may be due to chance or minor environmental differences. However, if the difference between two varieties is greater than the LSD, there is a 95% or better probability that the performance is actually different.

Selecting a Variety

The primary consideration in selecting a variety is harvestable yield. When evaluating a variety, consider yield performance over several years, if available. Give preference to data obtained in the nearest variety trial. Use all trials in determining a variety's performance under various environmental conditions.

Considerations other than yield are important in selecting a variety, and in some cases result in choosing a variety with only moderate performance. It is especially important to select a variety with a proper maturity. From past weather data, farmers can determine the percent probability of the time of the first fall frost. A general rule of thumb is to choose a variety that will mature (see maturity date definition) before the average date for 25% chance of the first killing frost in the fall. Farmers growing soybeans for the first time may wish to contact neighbors to determine what varieties mature before frost in their area. When large acreages of soybeans are planted, varieties of different maturities provide staggered maturity dates for a longer harvest season.

The degree of lodging varies among varieties. Lodged plants in variety trials are manually picked up and threshed, thus potential yield losses from lodging are not reflected in the yields reported. Lodging ratings should be used to evaluate potential losses. Farmers who have experienced lodging in the past and have had harvest problems may want to select a more lodging-resistant variety. Alternately, a variety susceptible to lodging may be planted at a slightly lower population to increase standability. Evaluate lodging data over all locations to determine a variety's lodging characteristics.

Note seed size when selecting planting rates. Planting rates based on number of seeds per foot of row eliminate seed-size bias.

Many diseases occur in soybean fields in Michigan. The diseases which contribute most significantly to yield reduction are seed and seedling diseases and those causing root and stem rot. Root rots of soybeans are generally recognized when plants turn yellow prematurely, wilt, or die. Less noticeable is the yield reduction that occurs when root rot destroys part of the root system, but causes no visible symptoms to aboveground parts. The fungi that cause root rots often survive in the soil for several years, even in the absence of a host plant. Once root rot fungi are established in a field, control is difficult, even with crop rotation.

New varieties with resistance to one or more diseases are being developed, particularly varieties resistant to *Phytophthora* root rot. Consult seed dealers or Cooperative Extension Service personnel for information on varietal disease resistance characteristics.

It is often beneficial for growers to select a few good varieties for planting each year. Yield determination and careful field evaluation during the growing season will add to the grower's knowledge of varietal performance and allow better selection in following years.

More information about variety selection and cultural practices can be found in Extension Bulletin E-1549, "Soybean Production in Michigan" (free).

Use of Data

All data presented are from 1983 performance trials, except the 1982-83 and 1981-83 yield averages. The varieties are arranged in order of yield within a maturity trial at each location.

The presentation of data for the entries tested does not suggest approval or endorsement of varieties by

the authors or by those responsible for conducting the performance trials.

The MSU Cooperative Extension Service approves the reproduction of the information in this publication only if no portion is deleted, if the data is not rearranged or otherwise manipulated and if appropriate credit is given.

 E: ELIGIBLE FOR CERTIFICATION IN MICHIGAN
 EO: ELIGIBLE FOR CERTIFICATION FOR OUT-OF-STATE SALE ONLY
 R: RECOMMENDED IN MICHIGAN

MSU is an Affirmative Action/Equal Opportunity Institution. Cooperative Extension Service programs are open to all without regard to race, color, national origin, sex, or handicap.
 Issued in furtherance of cooperative extension work in agriculture and home economics, acts of May 8, and June 30, 1914, in cooperation with the U.S. Department of Agriculture. Gordon E. Guyer, Director, Cooperative Extension Service, Michigan State University, E. Lansing, MI 48824.

This information is for educational purposes only. Reference to commercial products or trade names does not imply endorsement by the Cooperative Extension Service or bias against those not mentioned. This bulletin becomes public property upon publication and may be reprinted verbatim as a separate or within another publication with credit to MSU. Reprinting cannot be used to endorse or advertise a commercial product or company.
