All hybrids were randomized and compared in the same field using the same procedure. Table 22 presents an index of all hybrids entered in the 1970 trials.

Single-cross hybrids are indicated with (2X), three-way hybrids with (3X) and special cross hybrids with (Sp) following the hybrid name and number in the tables. All others are double-cross hybrids.

Michigan experimental hybrids are not listed since seed is not yet available for farm use.

METHODS

Scientific procedures are followed in conducting these trials to give all hybrids equal opportunity to demonstrate their capabilities. The best way to compare a group of corn hybrids is to grow them in the same field with the same fertilizer, population, date of planting, etc., for all hybrids.

Seed for Voluntary and Extension entries was submitted by seed companies. An equal number of seeds were counted for each plot of all hybrids. Each hybrid was replicated several times in the field. Plots were planted with a standard two-row or four-row corn planter adapted for small plots.

From seed packaging through harvest and data processing, each hybrid was identified only by a code number to reduce the chance of personal bias by anyone working in the field or with the data. The code was deciphered after the data had been processed.

Stands and lodging were counted before harvest. Plots for grain yields were harvested with a one-row picker-sheller. Field data were processed with high-speed electronic computers.

Silage yields were taken on all hybrids in the Ingham, Huron, Alpena and Alger County trials (Tables 10, 15, 20, 21).

High-lysine opaque-2 hybrids were tested in comparison with some normal dent hybrids in Ingham County (Table 11).

Blight ratings were made at most locations in late August and early September. These are discussed in a later section of this bulletin.

All hybrids in the Monroe, Ingham and Saginaw County trials were compared at two plant populations (Tables 1, 8, 13). Yields from 36-, 30- and 18-inch row spacings for the Ingham County trial are given in Table 9.

Irrigated and non-irrigated comparisons were made in the Montcalm County trials (Table 16).

There were two locations in Cass County — upland soil with irrigation (Table 5) and muck soil (Table 6).

Planting of all trials was completed between April 28 and May 22.

Normal rainfall in most areas of the state during the spring favored timely planting. The Michigan Crop Reporting Service estimated that about two-thirds of the corn acreage was planted by May 20 and 85% by the end of May — the earliest since 1963.

Rainfall during June and July was above normal at most locations and light during August. Leaf blights (Southern, Yellow and Northern) developed in most areas with heavier infections in southern Michigan. Infections developed too late to cause serious damage in most fields. Stalk lodging was above normal.

Corn matured earlier than usual due to earlier planting and a favorable growing season. Leaf kill by blights gave an appearance of earlier maturity. Most corn was matured before the first general killing frost on Oct. 16 and 17. Harvest proceeded rapidly with 60% harvested by the end of October compared to only 30% harvested by Oct. 31, 1969. Rains and wet fields slowed harvest in November.

Dry weather damaged the Grand Traverse County trial and it was abandoned. Table 18 presents 1969, 1968 and 1967 data with no results from 1970.

Yields at the 14 testing locations averaged 3.2 bushels less than in 1969 — 109.5 vs. 112.7. Higher yields were obtained at Monroe, Saginaw, Sanilac and Huron County trials in 1970 with lower yields at the other locations compared to 1969.

The Michigan Crop Reporting Service estimates the 1970 state average corn yield at 80 bushels per acre (highest on record; previous high was 76 bushels in 1968); 1,393,000 acres were harvested for grain. This compares with 74 bushels per acre on 1,266,000 acres in 1969 and 1968 averages of 76 bushels per acre on 1,266,000 acres. In addition, about 450,000 acres of corn are harvested for silage.

HOW TO USE THIS BULLETIN

One-, two- and three-year averages are presented for all hybrids tested during 1970, 1969 and 1968. One-year data are less reliable than two- or three-year averages and should be interpreted with more caution. Confidence in corn performance data increases with the number of years and locations of testing. Two or more years' results are more desirable than one year of testing.

The tables tell you three things about the hybrids tested:

1. average moisture content at harvest,
2. average yield in bushels of shelled corn at 15.5% moisture or silage yields, and
3. average percentage of stalk lodging (plants broken below the ear at harvest).

Hybrids are recorded in the tables in order of their approximate maturity (early to late) based on moisture content at harvest. Moisture content was determined from shelled grain samples at all locations harvested for grain and from ear corn samples in the silage trials.

Stalk breakage is caused by corn borers and/or stalk rot diseases.

Two or more plots of the same hybrid in the same field may produce somewhat different results due to

uncontrolled variability in the soil and other environmental factors. Replication and randomization of the entries are two methods used to reduce these errors. Since these methods do not eliminate all of these effects, differences necessary for statistical significance have been calculated for yield and moisture content.

When comparing any two hybrids, the difference between them should not be considered significant unless it exceeds the value listed as "least significant difference", at the bottom of the tables.

Agronomic information for each trial is given at the bottom of the table. Fertilizer amounts are total pounds per acre of nitrogen, P_2O_5 and K_2O applied during the season.

HOW TO CHOOSE A HYBRID

Adaptation — The map on the cover shows the location of the trials and divides Michigan into four maturity zones. A map can show maturity zones only in a general way. Local variations in weather, soil type and fertility, time of planting, and other conditions all affect adaptation. Corn hybrids are often adapted to more than one zone.

Find the zone in which you plan to grow the corn, and refer to the table which gives results for the trial conducted nearest your farm. Also, refer to the other tables listed in your zone. A hybrid which has done well at two or more locations is more likely to be a good hybrid for your farm, too.

Planting Rate — A population of 12,000 plants per acre is best for corn soils producing 50 bushels or less per acre. Populations of 16,000 to 18,000 are best for soils producing more than 50 bushels per acre. Higher populations (20,000 or more) should be considered only for soils consistently producing more than 100 bushels per acre. Rainfall deficiencies with high plant populations usually result in no increase and frequently a decrease in yield compared to 16,000 to 18,000. Lodging and harvest losses are often greater at high populations.

Maturity — Hybrids are listed in the tables in order of maturity — early to late — based on moisture content of the grain at harvest. This is usually a reasonably accurate measure of relative maturity in most years in Michigan. Early maturing hybrids will be generally lower in moisture content than later maturing hybrids. Differences among hybrids in rate of drying in the field also affects moisture content at harvest but usually does not greatly disturb the relative maturity ratings as determined by moisture content.

Due to blight and unusually rapid drying in the field in 1970, moisture contents do not appear to be as good a measure of relative maturity as usual. Early and medium-early hybrids appear to have dried down to a low moisture and remained there while

later maturing hybrids dried down to moistures approaching those of the early hybrids. Thus, the spread in moisture content between early and late maturing hybrids was less and there appears to be more-than-usual interactions with rate of drying.

One percent more moisture at harvest means a delay in maturity of about two days. Corn is mature when moisture is down to about 32% in the grain or 38% in the ear.

For Grain — It is better to choose an early corn (below average moisture content) than a late corn for grain. The tables show that good yields do not depend on later maturity. Advantages of early-maturing hybrids are:

1. They usually mature before killing frosts.
2. Good-yielding early hybrids generally yield as much or more corn than late hybrids in most areas in Michigan.
3. Lower moisture content at harvest permits safer storage. You will take more clean, sound, high-quality corn out of the crib.
4. Mature, dry corn makes better livestock feed.
5. You can harvest earlier in the fall when weather conditions are most favorable. Early harvest may reduce corn losses resulting from broken stalks and dropped ears in the field.
6. Early hybrids with lower moisture content at harvest reduce drying costs and market discounts for moisture.
7. Fall plowing of corn stubble may be possible with early hybrids on land not subject to erosion.

For Silage — The best silage contains a high percentage of grain. Hybrids that produce high yields of grain should be used for silage. High dry-weight production per acre is a better basis for choosing hybrids for silage than tons of green weight.

Corn for silage should reach the early dent stage well before frost in an average year. The early dent stage, when most of the kernels have dented, is the best time to begin harvest for silage. Dry matter production continues to increase until maturity.

Other Considerations — Choose early hybrids for late plantings, low soil fertility, sandy soils, muck soils and for corn which is to be followed by a winter grain or cover crop.

You can get some degree of "crop insurance" by choosing two or three hybrids which differ slightly in their maturity. If one hybrid runs into unfavorable weather at a critical stage of growth, another may be affected less and come through with a good crop.

Even though you have been growing a hybrid which has given good results, you may be able to improve your corn crop by trying one or more of the hybrids with better records in these trials. Well-tested, new hybrids are worth trying. You may want to try a new hybrid in a strip in the same field with your present hybrid.

BLIGHT RATINGS

Blight ratings were made for all hybrids at most locations in late August and early September, 1970. A rating scale of 1 to 6 (1 = no blight and 6 = heavy blight) was assigned to each plot and averaged for all replications of each hybrid. Ratings of 1-2 can be considered relatively resistant, 3-4 = moderately resistant, and 5-6 = susceptible. Small differences, less than 1.0, between hybrid ratings should not be considered significant.

It was impossible to distinguish between lesions caused by the new "T" race of Southern Corn Leaf Blight (SCLB) and Yellow Leaf Blight (YLB) in the field. Both were present in Michigan in 1970. Northern Corn Leaf Blight was also present at all locations and an attempt was made not to include it in the blight rating.

Most hybrids were susceptible to blight. The majority were hybrids with sterile cytoplasm which is generally susceptible to the new "T" race of SCLB and also tends to be more susceptible than normal cytoplasm to YLB. Some hybrids were a blend of normal and sterile cytoplasm. Blended hybrids did not show a marked difference in blight resistance at the time these ratings were made. Hybrids with normal cytoplasm were more resistant than sterile or blended hybrids but none of them were completely free of blight infection.

Seed for 1971 planting of some of these hybrids may be in a different cytoplasm from that used in 1970 so that the blight ratings presented here represent only 1970 conditions. For 1971, most seed corn bags will have a special tag labeled either "N" (normal cytoplasm), "B" (blend of normal and sterile cytoplasm) or "T" (sterile cytoplasm). "N" seed will probably be more resistant to the "T" race of SCLB than either "B" or "T" seed. Fields planted with "B" seed will probably have $\frac{1}{3}$ - $\frac{1}{2}$ of the plants with some resistance and the other $\frac{2}{3}$ - $\frac{1}{2}$ of the plants

will be more susceptible. "T" seed will probably be more susceptible than either "B" or "N" types. The differences in blight resistance due to seed type are less clear cut for YLB than for the "T" race of SCLB.

USDA estimates of seed for 1971 indicate that about 22% of the total seed supply will be "N", 38% will be "B" and 40% "T". Most of the "N" and "B" seed will be used in other states where blight was more of a problem in 1970 so that Michigan will need to use relatively more "T" seed. There should be adequate supplies of "N" seed of most hybrids for 1972 planting.

Yields of hybrids in these trials did not appear to be related to their blight ratings. Some hybrids with susceptible ratings, 5 and 6, had as good or better yields than hybrids with more blight resistance. The best yielding hybrids were not necessarily the most blight resistant.

Assuming that blight will be no worse or less of a problem in 1971 in Michigan and considering the shortage of "N" and "B" seed, the following suggestions are prescribed for consideration in choosing corn hybrids for 1971:

1. Continue to choose hybrids on the basis of their current performance — high yield, proper maturity and lodging resistance.
2. Do not switch to hybrids with unknown performance or with later maturity just to obtain "N" or "B" seed. Losses due to poor performance and immature corn may exceed any advantage of blight resistance.
3. Do not plant F_2 (second generation) seed saved from "N" cytoplasm commercial fields in 1970. F_2 seed of single-cross hybrids will average 30% or more lower yield than F_1 seed and 15% or more lower yield for three-way and double-cross hybrids. The expected loss in yield from planting F_2 seed will probably be greater than the loss from blight.

Table A. Average, highest, and lowest moisture content, yield, and stalk lodging at 14 locations in 1970.

1Significantly better than average yield at 19,800 population in 1970.

2Significantly better than average yield at 26,000 population in 1970.

1970
Planted May 7
Harvested Nov. 4
Soil type Brookston clay loam
Previous crop Tomatoes
Population 19,800 and 26,000
Rows 30"
Fertilizer 123-132-132
Soil test: pH 6.8
P 33 (medium)
K 165 (medium)

1969
Planted May 26
Harvested Nov. 4
Soil type Brookston loam
Previous crop Corn
Population 19,500 and 25,600
Rows 30"
Fertilizer 193-102-156
Soil test: pH 6.9
P 39 (high)
K 274 (high)

1968
Planted May 8
Harvested Oct. 15
Soil type Brookston clay loam
Previous crop Corn
Population 19,100 and 25,800
Rows 30"
Fertilizer 112-128-182
Soil test: pH 6.5
P 99 (very high)
K 242 (high)

Farm Cooperator: 1970 = Harley Lievens, Riga; 1969 and 1968 = Earl Creech, Dundee

County Extension Director: Paul Nevel, Monroe

1Significantly better than average yield at 20,000 population in 1970.

2Significantly better than average yield at 25,100 population in 1970.

1970
 Planted April 28
 Harvested Oct. 2
 Soil type Conover clay loam
 Previous crop Corn
 Population 20,000 and 25,100
 Rows 36"
 Fertilizer 158-85-85*
 Soil test: pH 6.4
 P 95 (very high)
 K 199 (high)

1969
 Planted May 5
 Harvested Oct. 8
 Soil type Conover clay loam
 Previous crop Corn
 Population 19,400 and 24,900
 Rows 36"
 Fertilizer 185-70-70*
 Soil test: pH 7.0
 P 41 (high)
 K 224 (high)

1968
 Planted May 4
 Harvested Oct. 5
 Soil type Conover clay loam
 Previous crop Corn
 Population 19,500 and 25,000
 Rows 36"
 Fertilizer 150-60-60
 Soil test: pH 6.6
 P 59 (high)
 K 315 (high)

Farm Cooperator: Michigan State University, East Lansing

*Acknowledgment: Anhydrous ammonia donated by Klein Fertilizer Co., Fowlerville, Michigan

Table 22. Index for 267 hybrids entered as 1,067 entries in the 1970 Michigan Corn Performance Trials. Numbers within parentheses refer to table numbers in which the hybrid appears; (2X) indicates a single-cross hybrid, (3X) indicates a three-way hybrid, (Sp) indicates a special-cross hybrid, and all others are double cross hybrids.
