Production

RED

**BY: E. C. Rossman, Keith Dysinger, Mervin Chamberlain, R. H. Leep,
Oran B. Hesterman and Francis J. Pierce**

Authors are, respectively, Professor, Research Technician, Research Aide, Associate Professor and Assistant Professors, Crop and Soil Sciences Department.

Hybrid corn trials are conducted each year by the Michigan Agricultural Experiment Station in cooperation with the Cooperative Extension Service, seed corn companies and farmers.

Many different hybrids are offered for sale in Michigan. They differ in yield ability, maturity, lodging resistance and other characteristics. Choosing the best corn hybrids is an important part of profitable corn production. By planting the best hybrids, farmers can obtain higher yields and other improvements with little or no increase in production costs. Seed of the best hybrids generally costs no more than seed of hybrids with lower performance.

The highest yielding hybrids in the 1985 trials produced 31 bushels more corn per acre than the average of the 418 hybrids tested (Table A). At the 21 testing locations, the yields were 163 bushels for the highest, 132 bushels for the average and 104 bushels for the lowest yielding hybrids. The driest hybrids at harvest contained 5 percent less moisture than the average and 10 percent less moisture than the wettest hybrids tested. Stalk breakage averaged 9 percent for hybrids with the highest amount of stalk lodging, 2 percent for the average and 0.1 percent for the lowest.

Entries

All seed companies are invited to enter hybrids in the trials each year. A fee is charged to cover some of the direct expenses.

Table 28 presents an index of all hybrids entered in the 1985 trials. At the 21 locations, 418 hybrids were tested as 2,219 entries. Company names used in association with hybrid numbers refer to the brand; the number is the hybrid designation. Single-cross hybrids are indicated with (2X), three-way hybrids with (3X), double-cross hybrids with (4X), modified single-cross hybrids with (MSX) and special cross hybrids with (Sp) following the hybrid name and number in the index, Table 28.

Methods

Scientific methods are used to conduct these trials to give all hybrids equal opportunity to demonstrate their capabilities. The best way to compare a group of corn hybrids is to grow them all in the same field with the same fertilizer, population, date of planting, etc.

Seed companies submitted seed for all entries. Equal numbers of seeds were counted for each plot of all hybrids. Each hybrid was replicated several times in the field. Plots were planted with a standard, two-row corn planter adapted for small plots.

From seed packaging through harvest and data processing, each hybrid was identified only by a code number to reduce the chance of biased results. The code was deciphered after the data had been processed.

Stands and lodging were counted before harvest. Plots were harvested mechanically for both grain and silage yields.

Silage yields were taken on all hybrids in trials of Ingham, Sanilac, Huron, Missaukee, Alpena, Menominee and Alger counties (Tables 11, 14, 17, 22, 24, 26 and 27). The Sanilac County silage trial was on a different farm than the grain trial.

Irrigated and non-irrigated comparisons were made in the Montcalm County trial (Table 19). There were two locations in Cass County — upland soil with irrigation (Table 6) and muck soil (Table 7). Trials in Hillsdale and Mason counties (Tables 2 and 20) were also irrigated.

Growing Conditions

All planting was completed between April 26 and May 22. Favorable weather during planting resulted in good stands and rapid emergence. Early plant development was two weeks ahead of normal. Rapid growth continued until early August when moisture stress slowed development

to below normal. The crop was 55 percent silked by July 28, slightly ahead of normal.

Soil moisture supplies became short during late July and most of August. Scattered rains during mid-August with heavy rains in late August and early September relieved most of the moisture stress. Crop development had fallen behind normal during the stress period. Corn was 40 percent dented by September 8 compared to 60 percent in 1984 and 63 percent for the 5-year average.

Plant height was generally shorter than normal, but late rains helped grain development and yields were higher than expected. Maturity and dry down were slower than normal.

A premature killing frost occurred in late September at the Cass County muck soil plots, which caused some reduction in yield. An early killing frost at the Alger County location in the Upper Peninsula made harvest for grain impractical. Silage yields are reported in Table 27.

Rain and wet fields during October and November slowed harvest. Harvest of overstate research plots was completed between October 17 and November 7.

Total corn acreage was 3,100,000 with 2,700,000 acres harvested for grain and 400,000 acres for silage. The Michigan Crop Reporting Service estimates a state average yield of 102 bushels per acre, second highest on record for Michigan. The previous high was 107 in 1982 and compares with 84 in 1984 and 92 in 1983. Total grain production is estimated at 275,400,000 bushels.

Plant Population Trials

Five adapted hybrids at 4 plant populations (16,400 to 28,200 plants per acre at harvest) were grown at each of 17 locations (Table B). Hybrid x population interactions were not

significant, so only the averages are reported.

The 24,400 average harvest population produced significantly higher yields at 10 of the 17 locations, averaging 160 to 202 bushels per acre. These increases were 16, 14, 14, 15, 9, 6, 9, 12, 11 and 8 bushels per acre above yields at 20,500 population. Four of these 10 locations were irrigated. Yields decreased (5 to 13 bushels) at 7 locations when harvest populations increased from 20,500 to 24,400.

Average yields were 136, 149, 153 and 143 bushels per acre for the 4 populations averaged for all locations. Moisture content of grain averaged 1 to 2 percent higher for the highest population. There was a trend toward increased stalk lodging as plant population increased.

No-Till Trials

Hybrid corn trials were conducted with a no-till production system at two locations — Kellogg Biological Station (KBS) in Kalamazoo County and Michigan State University (MSU) in Ingham County (Tables 5 and 12). Cooperators were Drs. Oran B. Hesterman and Francis J. Pierce of the Department of Crop and Soil Sciences. These trials were not part of the open-entry, fee-assessed trials represented in this report. Selection of hybrids was made by E. C. Rossman.

Eighteen hybrids were grown without irrigation in a comparison of no-till vs. conventional tillage at MSU. Yields for no-till corn were significantly lower than those for conventional tillage (moldboard plow). Yields listed in Table 12 are from no-till plots.

Fifteen hybrids, planted no-till and conventional tillage, irrigated and non-irrigated were evaluated at KBS. Yields for the two tillage systems and irrigation were not significantly different. Yields listed in Table 5 are averages for irrigated and non-irrigated no-till.

How To Use This Bulletin

One-, two- and three-year averages are presented for all hybrids tested during 1985, 1984 and 1983. One-year data are less reliable than two- or three-year averages and should be interpreted with more caution. Confidence in corn performance data increases with the number of years and locations of testing. Two years' results or more are more desirable than one year's.

The tables show the following about the hybrids tested:

1. Average moisture content at harvest.
2. Average yield (in bushels) of shelled corn at 15.5 percent moisture.
3. Average percentage of stalk lodging (plants broken below the ear at harvest).

Hybrids are recorded in the tables in order of their approximate maturity (early to late) based on moisture content at harvest.

Moisture content was determined from shelled grain samples at all locations harvested for grain and from chopped silage (fodder plus grain) in the silage trials.

Stalk breakage is caused by corn borers and/or stalk rot diseases.

Two or more plots of the same hybrid in the same field may produce somewhat different results due to uncontrolled variability in the soil and other environmental factors. Replication and randomization of the entries are two methods used to reduce these errors. Since these methods do not eliminate all of these variables, differences necessary for statistical significance have been calculated for yield and moisture content.

When comparing any two hybrids, the difference between them should not be considered significant unless it exceeds the value listed as "least significant difference" at the bottom of the tables.

Hybrids with yields significantly better than the

average grain yield at each location are marked with an asterisk (*) in each table. The least significant difference for yield was added to the average yield. Hybrids exceeding this yield are starred. There are some statistically significant differences among hybrids significantly better than average yield in 1985.

Agronomic information for each trial is given at the bottom of each table. Fertilizer amounts are total pounds per acre of nitrogen, P_2O_5 and K_2O applied during the season.

How To Choose A Hybrid

Adaptation

The map on the cover shows the location of the trials and divides Michigan into four maturity zones. The map shows maturity zones only in a general way. Local variations in weather, soil type and fertility, time of planting and other conditions all affect adaptation. Corn hybrids are often adapted to more than one zone.

Find the zone in which you plan to grow the corn, and refer to the table that gives results for the trials conducted nearest you. Also, refer to the other tables listed in your zone. A hybrid that has done well at two or more locations is more likely to be a good hybrid for your farm, too.

Planting Rate

High plant populations (20,000 or more per acre) should be considered only for soils consistently producing more than 100 bushels per acre. Rainfall deficiencies with high plant populations usually result in no increase in yield, and frequently a decrease, compared to 18,000 to 19,000 plants per acre. Lodging and harvest losses are often greater at higher populations.

Maturity

Hybrids are listed in the tables in order of maturity (early to late) based on moisture

content of the grain at harvest. This is usually a reasonable, accurate measure of relative maturity in most years in Michigan. Early-maturing hybrids are generally lower in moisture content than later-maturing hybrids. Differences among hybrids in rate of drying in the field also affect moisture content at harvest, but usually do not greatly disturb the relative maturity ratings as determined by moisture content.

One percent more moisture at harvest means a delay in maturity of about two days. Corn is mature when moisture is about 32 percent in the grain or 38 percent in the ear.

For Grain

It is better to choose an early corn (below average moisture content) than a late corn for grain. The tables show that good yields do not depend on later maturity. Advantages of early-maturing hybrids are:

- They usually mature before killing frosts.
- Good-yielding early hybrids generally yield as much or more than late hybrids in most areas in Michigan.
- Early hybrids with lower moisture content at harvest reduce drying costs and market discounts for moisture.
- Mature, dry corn makes better livestock feed.
- You can harvest earlier in the fall when weather conditions are most favorable. Early harvest may reduce corn losses resulting from broken stalks and dropped ears.
- Fall plowing of corn stubble may be possible with early hybrids on land not subject to erosion.

For Silage

The best silage contains a high percentage of grain. Hybrids that produce high yields of grain should be used for silage. High dry-weight

production per acre is a better reason for choosing hybrids for silage than tons of green weight.

Corn for silage should reach the early dent stage well before frost in an average year. The early dent stage, when most of the kernels have dented, is the best time to begin harvest for silage. Dry matter production continues to increase until maturity.

Other Considerations

Choose early hybrids for late plantings, low soil fertility, sandy soils, muck soils and for corn that is to be followed by a winter grain or cover crop.

You can obtain some degree of "crop insurance" by choosing two or three hybrids that differ slightly in their maturity. If one hybrid runs into unfavorable weather at a critical stage of growth, another may be less affected and produce a good crop.

Even though you have been growing a hybrid that has given good results, you may be able to improve your corn crop by trying one or more hybrids with better records in these trials. Well-tested, new hybrids are worth trying. You may want to try a new hybrid in a strip in the same field with your present hybrid.

Ways To Reduce Stalk Lodging

Several stalk-rotting fungi may cause broken stalks at harvest and create a major problem in corn production. Stalk rot occurs when fungi increase rapidly after the plant has matured or when the plant has died prematurely. Highest incidence of stalk rot occurs in years when corn matures early and when harvest is delayed. Infection and disease development are favored by warm, humid weather and abundant rainfall during the latter part of the growing season.

Hybrid resistance to stalk rot is only one of several factors that determine the extent of stalk

breakage. There are no clear-cut cases of specific hybrids that can be depended upon consistently to resist stalk rot under all conditions of soil fertility, plant population, plant stress and maturity. A major part of the difference in resistance to lodging appears to be mechanical — stiffer stalks do not break as soon when disease attacks.

The most effective practice to reduce losses from stalk rot is to harvest as soon as possible after maturity. Stalk breakage continues to increase rapidly in warm, damp weather when harvest is delayed. Early-maturing hybrids that mature in September will have more stalk breakage than late-maturing hybrids harvested in November and December. There may be little or no advantage to planting early-maturing hybrids if harvest is delayed.

To avoid problems, choose high yielding, early maturing hybrids, plant early and harvest early.

Ways To Avoid Moldy Corn In 1986

Use the following recommendations to help prevent moldy corn in 1986:

- Plant early.
- Plant early to medium-early maturing hybrids.
- Harvest early — during October. Weather problems and harvest losses increase with later harvest.
- Plan for adequate artificial drying. Drying in the field and in the crib is slow and undependable in Michigan. Ready access to drying facilities will permit more timely harvest, prevent high harvest loss and produce greater corn profits.

Seed Supplies For 1986

Production of hybrid seed corn in 1985 was good to very good. Seed supplies of most hybrids should be adequate for 1986 planting.

TABLE 28

Index for 418 hybrids entered as 2,219 entries in the 1985 Michigan Corn Performance Trials. Numbers within parentheses refer to table numbers in which the hybrid appears. (2X) indicates a single-cross hybrid, (3X) indicates a three-way hybrid, (4X) indicates a double-cross hybrid, (MSX) indicates a modified single-cross and (Sp.) indicates a special-cross hybrid. Company names used in association with hybrid numbers refer to the brand and the numbers are the variety (hybrid) designation.

AgriPro, Mission, KS 66201

AgriPro AP244 (2X) (2,4,7,8,9,10,11,13,14,15)	AgriPro HP401 (2X) (3,7,8,9,10,11,13,14,15)
