2008

MICHIGAN CORN PERFORMANCE TRIALS

*K. Thelen, K. Dysinger, L. Williams and W. Widdicombe
Department of Crop and Soil Sciences
Michigan State University*

Introduction

The Michigan State University Department of Crop and Soil Sciences conduct hybrid corn trials each year in cooperation with MSU Extension, seed corn companies, and farmers to determine performance.

Entries

Seed companies are invited to enter hybrids in the trials and a fee is charged to cover expenses. Separate indexes for grain and silage provide a list of all hybrids entered in the 2008 trials (pg. 26 and 31, respectively). Fourteen grain and ten silage locations were planted. A total of 331 hybrids from 24 seed companies (25 brand names) make up the 606 entries which translates to 7,112 separate county plots. Company names used in association with hybrid numbers refer to the brand. The hybrid numbers are the companies designations. Numbers in parentheses refer to the tables in which each hybrid appears.

Hybrids that have a seed-applied insecticide that may enhance yield are listed in the table column TRT (Treatment). The TRAIT column, uses code numbers, listing the hybrid quality traits provided by the company. Treatment and Trait codes are listed in the tables on page 21.

How to Use This Bulletin

Tables list hybrids alphabetically and contain yield results for each location, plus zone averages. Complete one- and two-year yield results are listed in tables for each zone where data is available. One-year single-site results are less reliable than multiple year and multiple location averages, and should be interpreted with more caution. Confidence in corn performance data increases as the number of years and the number of testing locations increase. Results are also listed on our Web site:

<http://www.css.msu.edu/varietytrials/>

The results shown are the average of four replications grown in close proximity to one another. Two or more plots of the same hybrid in the same field may produce somewhat different results because of uncontrolled variability in the soil and other environmental factors.

Replication and randomization of the entries are two methods used to reduce this variation. Because these methods do not eliminate all variables, the magnitude of difference necessary for statistical significance has been calculated for yield, moisture content, and test weight. The value calculated as the least significant difference (LSD) is the amount that an individual hybrid would have to differ from another hybrid in the same test to be considered significantly different from that hybrid. The CV, or coefficient of variability, is indicative of a trial's precision. Trials with low levels of error variation have lower CV values.

Hybrids that are not significantly different from the highest yielding hybrid are marked with an asterisk (*) in each table (highest yielding hybrid is marked with **). Other agronomic information relative to each trial is given in tables B and C. Fertilizer amounts are shown as total pounds per acre of nitrogen, P₂O₅, and K₂O applied during the season.

Growing Conditions in 2008

Mid April showers delayed early season plantings in 2008. Planting started April 24th and continued until May 21st. Six locations were planted in April. Locations needing Nitrogen applied had liquid 28% applied between June 2nd and June 27th. Silage harvest ran between Sept 3rd and Oct 2nd. Harvest started slowly and struggled for the first couple weeks. Delays in getting new equipment modifications added to the chopper slowed early season progress when the new modifications did not work properly. Those equipment delays and early season dry-down made for high Dry matter totals at early harvest sites in the Southern Zones. Mid September rainfall further delayed harvest. As harvest moved into the northern zones crop maturity was slowing down. In the end, Northern silage sites still had Dry matter totals in the low 30 percentile. Grain harvest started on October 20th in Cass County and finished in Montcalm County on November 20th. Rain and Mud made cause for a couple locations to have harvest completed at a second date.

Table A (pg. 5) presents 2008 accumulations of temperature, rainfall, and heat units, plus their deviation from 30 year norms. Data is obtained from MSU weather stations located closest to each location. Actual accumulation at each location may vary slightly.

2008 GROWING SEASON WEATHER SUMMARY

*Jeff Andresen, Extension Agricultural Meteorologist
Department of Geography
Michigan State University*

Weatherwise, the 2008 growing season in Michigan will likely be remembered most for cool temperatures early and for extended dryness during the second half of the season. Prior to the growing season, an upper air troughing pattern across the central U.S. and a very active storm track from the southern Great Plains through the Great Lakes Region led to a very snowy winter season in Michigan with much above normal snowfall totals in many areas. The above normal off season precipitation resulted in complete soil moisture recharge and abnormally wet soils across most of the state prior to the beginning of the season. One notable exception occurred in far northern sections of the state where below normal precipitation totals left soil moisture at below normal levels. As of early April, the Palmer Drought Severity Index categorized all of the Lower Peninsula as Unusually to Extremely Moist, with Mild Drought conditions for the Upper Peninsula.

Weather during spring planting in April and May was generally cooler and drier than normal, in response to persistent upper air trough across the Great Lakes Region. While the drier than normal conditions generally allowed fieldwork to progress, the cool temperatures slowed germination and early establishment of crops. A large Canadian-origin air mass centered over the central Great Lakes region brought widespread frost and freezing temperatures to Michigan the morning of May 28th, with sub-freezing minimum temperatures recorded across the majority of the state. The event was approximately 1-3 weeks later than the normal last freezing temperatures of the season and set new record lows for the date in some areas. The freeze was a radiation-type freeze event in which minimum temperatures varied greatly over only short distances. As a result of the strong spatial variability of minimum temperatures, a wide variety of damage and plant cold injury were reported, with replanting of crops necessary in some areas. In retrospect, the damage from this event could have been much greater since seasonal growing degree accumulations and resulting crop phenological development rates had been lagging at least a week or more behind normal.

By early June, a new jet stream pattern developed across North America with southwesterly flow across and a more active storm track through the Midwest. Heavy rain fell in many sections of the state in early and mid-June, with localized flooding and ponding in some cases. Frequent showers were a significant problem with forage harvest. Severe thunderstorms moved across southern sections of the state on the 2nd of July, bringing more heavy rain, flooding, and some damaging hail. Warmer than normal temperatures in late June and early July accelerated phenological development of crops following the cool start of the season.

A broad upper air ridging pattern developed across the region by mid-July and persisted through much of August. While mean temperatures remained close to slightly below the long term normals, rainfall in most of the state was well below normal. The drier than normal conditions led to crop moisture stress and ultimately to declines in yield potential across southern, western, and northern sections of the state. The lack of water was likely accentuated by the relatively shallow rooting depths of many crops due to the early wet,

cool conditions and was especially pronounced on lighter, coarse-textured soils. One very notable exception to the drier than normal pattern was an eastern area of the state from the Saginaw Valley through the Thumb, where precipitation was close to normal and in some cases even above normal.

The abnormally dry pattern was broken abruptly in most sections of the state in early September with the passage of the remnants of three separate hurricanes/tropical storms. While hurricanes and their remnants typically move poleward from tropical and subtropical origins at some point in their lifetime, it is somewhat unusual for them to impact Michigan and the Great Lakes region as the storms must make landfall in an area potentially upwind of the region and then upper air winds have to be just right to advect or transport the remnants here before the system completely dissipates. The first was Hurricane Gustav (or more precisely, its remnants), which initially made landfall in Louisiana and moved through Michigan on the 3rd and 4th of September. This system brought over 4.00 inches of rain to western sections of the Lower Peninsula. Because the rain with this system fell in a steady, moderate intensity over a several hour period, the vast majority of the precipitation soaked into the soil profile. On the 12th-14th, Michigan was visited by two more tropical systems, beginning with the remnants of Tropical Storm Lowell on the 12th. Just a day later, Hurricane Ike made landfall in the Galveston, Texas area. The southwesterly winds that brought the remnants of Lowell into the Midwest were still in place across the region, and Ike's remnants moved quickly north and eastward into the Great Lakes region early on the 14th with another round of heavy rain. Relatively strong winds (15-25 miles/hour with higher gusts) were still present with the system as it moved through southern Lower Michigan. Collectively, more than 10.00 inches of rain fell at some locations across the southwestern Lower Peninsula, leading to flooding and water-logged soils (and some new rainfall records). Unfortunately, the rainfall state was generally too late to be of major benefit to crops stressed by earlier dryness.

Overall for the 5 month May-September period, precipitation totals ranged from much below normal levels across northern sections of the state (the fourth consecutive year in which this has occurred) to much above normal levels across southern sections of the Lower Peninsula (due mainly to the heavy rains of early September). Mean temperatures and seasonal growing degree day accumulations were generally near to below the climatological normals. Many crops lagged somewhat behind normal phenologically as a result. Fortunately, the first killing freeze of the fall season was also later than normal over most areas of the state (except across northeastern sections of the state where freezing temperatures occurred during the second week of September), allowing an extended maturation and drydown period. It is also worth noting that while crop yields fell back to normal or below normal levels in many sections of the state due to the extended dryness in July and August, they were much above normal across east central sections of the state where precipitation during the middle of the growing season was much closer to normal.

2008 GRAIN PERFORMANCE TRIALS

Introduction

Fourteen locations (see map pg. 7) containing 29 grain trials were planted. The grain index (pg. 26) contains a list of all hybrids planted in the 2008 grain trials. Hybrids are reported in alphabetical order in each of the tables. County results are reported in the following tables:

Tables 1E/1L Zone 1 - Branch, Cass, and Lenawee

Tables 2E/2L Zone 2 - Ingham, Kent and Saginaw

Tables 3E/3L Zone 3 - Huron, Mason, and Montcalm

Table 4 Zone 4 Ogemaw, Grand Traverse, and Menominee (L)

Table 5 Zone 5 Delta and Menominee (E)

Tables 6E/6L Glyphosate Trial Huron (Zone 3), Montcalm (Zone 3), and Saginaw (Zone 2)

Methods

Three trial locations were planted in each of four maturity zones. Zone 5 had two locations. These zones are based on available growing degree-day units established from long-term weather records. Hybrids entered in a zone were tested in each of the three designated locations. Entries for Zones 1, 2, and 3 are divided into two maturity groups (early and late) on the basis of maturity ratings provided by the seed companies. In Zones 4 and 5, all hybrids were tested in one group.

Four-row plots were used at all grain locations. The two center rows were harvested for yield. Plots were 22 feet long with 30-inch row spacing.

Experimental design, data acquisition, analysis of variance and data summarization were facilitated in part by AGROBASE Generation II™ (Agronomix Software, Inc., Winnipeg, Canada). The experimental layout was a four-replication, lattice design. Hybrid performance is reported as the adjusted mean averaged together from four replicated plots.

Variety trials were conducted on farmers' fields. All hybrids in a location were managed the same, with the same fertilizers, population, date of planting, and other management practices. In the field, hybrids were identified only by a plot number to assure unbiased comparisons. Trials in Branch, Cass, Montcalm, and Mason counties were irrigated.

Stand counts were recorded in June. Plots with stand counts higher than the desired population were thinned at this time. Average trial population plus the desired population rates are listed with other important agronomic information in Table B (pg. 23). Lodging measurements were made at harvest. All plants broken below the ear and/or leaning more than 45 degrees were counted. Plots were harvested mechanically. Moisture content and field

weight were measured by a GrainGage™, a HarvestMaster System™ mounted on the plot combine. Grain yield is reported at a standard 15.5 percent moisture. Grain test weight is reported at harvest moisture. Automated test weight equipment loses some accuracy as harvest moistures increase. Test weight values should be used to determine relative rank and not as a precise weight.

Replicated grain samples were collected from one location in each zone (Branch, Ingham, Huron, Ogemaw, and Delta) and were tested for protein, starch and oil content using near infrared reflectance (NIR) quality analysis. The results are presented in each table.

Results

The tables report the following information about the hybrids tested:

1. Moisture content at harvest (%H₂O).
2. Yield (in bushels per acre) of shelled corn corrected to 15.5 percent moisture (Bu/A)
3. Test weight at harvest moisture (Twt).
4. Percent of stalk lodging (plants broken below the ear and/or 45 degrees off vertical at harvest) (%SL).
5. Percent stand of target population (%Std).
6. Percent protein (Prot), oil (Oil) and starch (%Strch) content are reported at 15.5 percent grain moisture.

How to Choose a Hybrid

Adaptation

The map on page 7 shows the locations of the grain trials and divides Michigan into five generalized maturity zones. Local variations in weather, soil type, fertility, time of planting, and other conditions all affect adaptation. Corn hybrids are often adapted to more than one zone.

In selecting a hybrid, there is no real substitute for observing individual characteristics while plants are growing. The best time to compare plants is usually in late August or early September as they approach maturity. Each year, demonstration plantings of each hybrid are planted at a limited number of test locations. In 2008, Hybrids were identified in Lenawee, Ingham, Ogemaw

and Grand Traverse Counties for public viewing with some having a scheduled field tour. Examining plant and ear characteristics can help you select hybrids suitable for your production system. (Yield results are not taken from the demonstration plot.)

Planting Rate

The number of seeds sown per acre in Michigan has increased steadily over the past several years. In general, modern corn hybrids can withstand the stress of higher plant populations better than hybrids of the past. However, increased planting rates are not a guarantee of increased yield. Check with your seed dealer for information on which hybrids perform better at higher populations when grown on your soil type.

Maturity

Early-maturing hybrids are generally lower in moisture content than later-maturing hybrids at harvest. Differences among hybrids in rate of dry down in the field also affect moisture content at harvest.

It generally requires two days for grain moisture to fall 1 percent under optimum drying conditions. Corn is considered physiologically mature when a black layer of cells forms at the base of the kernel. This black layer is an indication of the end of active growth processes. At this time, kernel moisture will be between 32 and 35 percent.

In 2008 Early-maturing hybrids averaged 2.1 moisture points below the later maturing hybrids at harvest in Zone 1 with a yield drop of just 2.1 Bushels over the trial average. Zones 2 and 3, had an average difference of 3.5 moisture points between early and late maturity hybrids while yield loss over the trial averages was .7 bushel in Zone 2 and 2.5 bushel in Zone 3. The Glyphosate resistant trial was 2.3 moisture points drier for the Early hybrids but showed the highest yield gain for late hybrids at 4.2 bushels. But would that yield gain cover drying costs and extra grain handling costs. In 2008 there appeared to be little advantage in growing later maturing hybrids.

For Grain

When you are selecting a hybrid, yield should not be the only consideration. A hybrid with lower grain moisture but above average yield will often have higher net returns than a top-yielding hybrid with higher grain moisture. A one-point increase in moisture requires approximately 2 more bushels in yield to break even. It is often better to choose earlier hybrids (below average moisture content) than later hybrids for grain. Data in the tables show that good yields do not necessarily depend on later maturity.

Seven Advantages of Early-Maturing Hybrids:

1. They usually mature before killing frost.
2. Adapted early hybrids can generally yield as much as late hybrids in most areas of Michigan.
3. Early hybrids with lower moisture content at harvest reduce drying time and market discounts for high grain moisture.
4. Grain test weights are generally higher, resulting in reduced market discounts.
5. Mature, dry corn makes a superior feed grain when used in swine or poultry rations.
6. Harvest can take place earlier in the fall, when weather conditions are most favorable reducing corn losses resulting from broken stalks and dropped ears.
7. Fall tillage of corn stubble can be completed on land not subject to erosion.

2008 Grain Trial Locations

HYBRID INDEX FOR GRAIN TRIALS

The 266 hybrids submitted for testing by 24 seed companies (25 brand names) resulted in 472 individual entries in the 2008 Michigan Corn Performance Trials for grain. The map of Michigan (page 7) shows each zone and the locations where the trials were located. Zones 1, 2 and 3 were divided into two maturity groups (designated early and late) on the basis of the maturity ratings (RM) submitted by the companies with results listed in separate tables. Below is a listing of company names, brand names, hybrid numbers, RM, and the table designation - an E (early) or L (late) for each hybrid.

2008 SILAGE PERFORMANCE TRIALS

Introduction

One Ohio and nine Michigan locations across five maturity zones (see map pg. 29) contained 17 silage trials. The silage index (pg. 31) contains the list of 116 hybrids submitted by 17 seed companies (19 brand names) totaling 134 individual entries. Zones 1, 2, and 3 have two maturity groups E or L based on company RM. In cooperation with The Ohio State University, the Wood County OH location is planted and managed by OSU while MSU handles harvest, plus quality and data analysis.

Hybrids are reported in alphabetical order in each of the tables. County results are reported in the following tables:

Tables 7E/7L Zone 1 - Branch, Lenawee and Wood (OH)

Tables 8E/8L Zone 2 - Huron (Zone 3), Ingham, and Kent

Table 9 Zone 4 - Ogemaw, Menominee (Late) and Osceola

Table 10 Zone 5 - Alger and Menominee (Early)

Results are also posted on our Web site:

<http://www.css.msu.edu/varietytrials/>

Methods

Testing procedures (randomization, replication, planting rates, etc.) for silage evaluation are the same as those utilized for the grain trials. For silage Agronomic information refer to Table C (pg. 30)

Silage plots were harvested with a two-row self-propelled forage harvester. Electronic scales mounted on the chopper measured plot weights. Total plot weight was used to calculate green tons per acre (**GT/A**). Sub samples of fodder plus grain were collected, weighed, oven dried until weight loss was zero, then weighed again to determine the percent dry matter (**%DM**). Dry tons per acre (**DT/A**) was calculated using **GT/A** multiplied by **%DM**. The samples were ground using a 1.0 mm screen before conducting quality analysis using NIR (near infrared reflectance).

Silage Analysis

Tables 7E, 7L, 8E, 8L, 9 and 10 provide silage quality data as determined by NIR analysis on freshly dried samples. Data is provided for individual locations and also averaged over multiple locations. Near infrared spectral analysis involves irradiating the ground sample with light in the near infrared spectrum (1,100 to 2,500 nm). The illuminated sample absorbs light proportional to specific chemical and physical properties. The reflected energy is measured and

correlated statistically with established forage quality levels. Results of the five quality traits analyzed are presented in the quality tables. The five quality traits are:

1. **IVD=(in vitro) digestible dry matter.** IVD is a measure of forage digestibility. Higher IVD is desirable.
2. **ADF=acid detergent fiber.** ADF represents the less digestible portion of the corn forage containing cellulose, lignin, and heat damaged protein. ADF is closely related to the digestibility of forages. Lower ADF implies the forage is more digestible. More mature plant material will contain higher ADF concentrations. A low concentration of ADF is desirable.
3. **NDF=neutral detergent fiber.** NDF is a measure of the fiber content of the corn forage. It is less digestible than non-fiber constituents of the forage. Forages with high NDF levels have lower energy. NDF is also a measure of potential forage intake. High NDF levels decrease the potential forage intake. Low NDF content is desirable.
4. **NDFD=neutral detergent fiber digestibility.** NDFD is the portion of neutral detergent fiber digested by animals at a specified level of feed intake. High NDFD is desirable.
5. **CP=crude protein.** Forages are generally supplemented with high protein concentrates such as soybean meal to increase the protein content of ruminant diets. Corn hybrids with high protein levels require less supplementation and therefore result in lower feed costs. High protein content is desirable.
6. **STRCH=starch.** Starch from the grain, along with the digestible component of the fiber, accounts for the majority of the energy in corn silage.

Silage quality traits are reported on a dry matter basis (100 percent DM). Quality traits in these tables are intended for use in hybrid selection only. Analysis for the balancing of feed rations should be analyzed from hybrids grown on each individual farm.

SILAGE HYBRID INDEX

The 116 hybrids submitted for testing by 18 seed companies (19 brand names) resulted in 134 individual entries in the 2008 Michigan Corn Performance Trials for silage. The map of Michigan (page 29) shows each zone and the locations where the trials were located. Zones 1 and 2/3 were divided into two maturity groups (designated early and late) on the basis of the maturity ratings (RM) submitted by the companies with results listed in separate tables. Below is a listing of company names, brand names, hybrid numbers, RM, and the table designation - an E (early) or L (late) for each hybrid

THANK YOU TO OUR FARM COOPERATORS:

Blaine Baker, Clayton
Blue Sky Farms, Lowell
Ed Breitmeyer, Buckley
Dave and Mel Cripe, Cassopolis
Brian Graff, MSU Agronomy Farm, East Lansing
Fred Gross Farms, Peggy Gross & Dick Birchmeier,
New Lothrop
Benny Herioux, Bark River
Kyle Huff, Coldwater
Dave Johnson, Daggett
Jorgensens Farm Elevator, Williamston
Robert E. Lee, Marion
Miller Feeds Inc., Prescott
Robert and August Oshe, Custer
OSU NW Experiment Station, Hoytville, Ohio
Pleasant Acre Farm, Caledonia
Bruce Sackett, Montcalm Research Farm, Entrican
Troy Sacket, Edmore
Wil-le Farms, Bad Axe
Jason Woods, Britton
Chris Kapp, UP Experiment Station, Chatham

THANK YOU TO OUR WORKERS:

Stephanie Smith, Graduate Student
Kate Withers, Graduate Student
Dan Dysinger
Ryan Rademacker
Sara Ward
Kelly Foote

MICHIGAN STATE
UNIVERSITY
EXTENSION

MSU is an affirmative action/equal opportunity institution. Michigan State University Extension programs and materials are available to all without regard to race, color, national origin, gender, religion, age, disability, political beliefs, sexual orientation, marital status, or family status. Issued in furtherance of MSU Extension work, acts of May 8 and June 30, 1914, in cooperation with the U.S. Department of Agriculture. Thomas G. Coon, director, MSU Extension, East Lansing, MI 48824. - This information is for educational purposes only. Reference to commercial products or trade names does not imply endorsement by MSU Extension or bias against those not mentioned. This bulletin becomes public property upon publication and may be reprinted verbatim as a separate or within another publication with credit to MSU. Reprinting cannot be used to advertise a commercial product or company.
