

Plant a Tree This Fall by James A. Fizzell, Sr. Ext. Adviser University of Illinois

The nip in the air tells us it is planting time again.

Providing cooling shade during hot summer months is just one of the benefits a tree provides. They act as insulators from city noise, dust and pollution. Just their presence softens the landscape, giving beauty and elegance to an otherwise sterile environment. And what is more restful to the soul than to listen to the gently rustling of leaves on a breezy summer night.

Trees provide home, restful haven, and sometimes food for the sparse city animal life — the squirrels and bird that children often appreciate more than do adults.

Perhaps most important, trees absorb much of the carbon dioxide pollution released by vehicles in the city and in turn release oxygen. In fact, an actively growing one acre grove of trees releases enough oxygen in one year to support 18 people.

Look around you. See what the proportion of trees to concrete and rooftops you see, and you will understand the need to plant trees.

Many trees do well in Chicago. Some are detailed below. NORWAY MAPLE. A broad, spreading shade tree that matures at 50-75 feet. Fall color is bright yellow. Shallow rooting makes it undesirable for planting near sidewalks, and its dense foliage makes it difficult to grow a lawn beneath the tree. Popular clones ("varieties") are 'Cleveland', 'Crimson King' (purplish-red summer leaves) and 'Greenlace'.

RED MAPLE. Another dense, spreading maple, growing to 60-80 feet high. Red flowers and fruit in spring are showy and attractive, as is its yellow to brilliant red foliage in the fall. Many clones do poorly in our alkaline soils. Common varieties often do better.

SUGAR MAPLE. Faster growing than Norway maple but slower than Red or Silver maple. Grows to 60-80 feet, with moderately dense foliage. Magnificent fall colors of golden yellow to orange to red. Best maple for shade tree use. Important clones are 'Columnare' and 'Green Mountain.'

OHIO BUCKEYE. Similar in appearance to the Horse chestnut but tree form is more rounded and uniform. Less disease prone than chestnut. Grows to 35-40 feet with large, attractive greenish-yellow flower clusters in the spring. Fall color is orange-red. Dropping fruits, loved by squirrels and used by children for necklaces and other crafts, may be messy for a short period in the fall.

RIVER BIRCH. Rapidly becoming a desirable substitute for the white birch because of its high resistance to bronze birch borer. A graceful tree of 60-75 feet with gently drooping branches. The exfoliating (rolled back) bark varies from near white to bronze. Fall color is yellow. A good tree for naturalized plantings.

KATSURA TREE. A magnificent tree reaching 60-100 feet and becoming wide-spreading when allowed to develop multiple trunks. Relatively pest free, with yellow to yellow-orange fall color.

AMERICAN AND GREEN ASH. The American reaches 75-80 feet; the Green 50-60 feet. Both have moderately dense foliage and are adaptable to a wide range of growing conditions. Fall color is basically bright yellow although the leaves of American ash may be mottled with purple.

Complete Water Supply Services From the Leading Water Supply Contractor.

- Pump Sales Line Shaft, Submersible, Fire
- Expert Pump Repair
- Well and Pump Preventive Maintenance Programs
- Engineered Water Well Construction
- Well Rehabilitation
- Aquifer Evaluation
- Complete Hydrology Services
- Exploration Drilling

Layne-Western Company, Inc.

721 West Illinois Avenue Aurora, IL 60506 Phone: 312/897-6941

LW-385

PRECISION BLENDED TOP DRESSING

Custom blended to your specifications by our modern equipment.

Buy when you need -Eliminate costly storage

We sell an air-dried, uniform and free flowing top dressing.

(Plant a Tree cont'd.)

HONEY LOCUST. An excellent adaptable tree where light shade or a grass carpet under the tree is wanted. Reaching 60-90 feet with a rapid growth rate, there are many seedless and thornless clones. A rugged but graceful city tree requiring little fall cleanup of its tiny yellow leaves. Some important clones are 'Imperial', 'Majestic', 'Moraine', 'Shade Master', and 'Skyline'.

RED OAK. Beautiful hardy tree reaching 60-100 feet. The Red oak is one of the best trees for ornamental planting here but must be planted in well-drained soil. Fall color ranges from red to brownish-red or brown.

LITTLELEAF AND SILVER LINDEN. Both are dense trees reaching 60-90 feet. Both are slow growing, but hardy. The foliage of Silver Linden is silvery underneath. Fall color is yellow for both.

Soil Amendments and Tree Establishment by Carl E. Whitcomb

Soil amendments have long been utilized in an attempt to modify soils on the planting site with the hope of improving tree growth and rate of establishment. Recommendations vary in terms of what should be used as a soil amendment and the rate or proportion of the material. Our original study was to determine the optimum amount of peat, vermiculite, ground pine bark or sand to be added at the time of planting to aid the establishment of trees and shrubs in the landscape. Over a 6-year period, five studies were conducted with varying rates and materials as soil amendments with and without irrigation and on three different soil types: a very sandy soil, a moderately good clay loam soil, and a very poor subsoil clay. The optimum amount of soil amendment to add was none. Pine bark was most detrimental to both establishment and growth followed by peat and sand. Vermiculite, although not beneficial when compared to no soil amendment added, was not as detrimental as were the other materials. When test plants were excavated, the root system in the amended soil treatments were confined primarily to the amended area, and few extended out into the surrounding soil. By contrast, where no soil amendment was used, the roots extended far beyond the original planting hole and thus were more well anchored and had a larger volume of soil to draw on for water and nutrients compared to the amended treatments. Adding additional fertilizer to the amended soil treatments was only slightly helpful in overcoming the growth restriction of the soil amendments. This is thought to be due to the nitrogen tie-up by the decomposition of the organic materials such as peat and ground pine bark. When studies were made of waterholding capacity, the amendments increased the amount of water held immediately following irrigation, however, after several weeks, the amended soils were dryer than those without amendments. This is probably due in part to the higher evaporation rate of the amended soils at the soil surface plus the fact that the root system of the test plant was confined almost entirely to the amended soil and was not drawing from surrounding soil moisture as was the case when no soil amendments were added. Peat and ground pine bark should not be used as soil amendments but can more effectively be used as a mulch on the soil surface to reduce soil temperature, soil erosion, and compaction.
