Brian Horgan  
University of Minnesota  
Kevin Frank  
Michigan State University

Objectives:
1. Evaluate the production of mineral N during incubation of soils differing in N fertilizer responsiveness.
2. Refine the critical amino sugar-N levels for turfgrass quality responsiveness.
3. Determine the impact of long-term fertility management practices on soil amino sugar-N values and nitrate leaching potential and to evaluate amino sugar-N concentration changes over time using the long-term N leaching plots at Michigan State University.

Start Date: 2010 (current cycle)  
Project Duration: 2 years  
Total Funding: $46,962

A USGA report “Nitrogen and phosphorus fate in a 10-year-old Kentucky bluegrass turf” authored by Frank (2005) has found leaching of 15N labeled urea bluegrass turf” authored by Frank (2005) reports that a 50% reduction in added fertilizer effectively eliminates nitrate leaching potential due to added fertilizer. In order to test this hypothesis, soil samples have been gathered from microplot lysimeters at Michigan State University for the years 2000-2010. Our goal with the analysis of these samples is to determine if the nitrate leaching events observed on the lysimeters at Michigan State can be correlated to changes in the amino-nitrogen level in the soil.

We expect to develop sampling procedure guidelines and interpretation of the ISNT results based on amino sugar-N and mineralization rates in order to make fertility reduction management recommendations on golf courses. We also expect to demonstrate that the ISNT can be utilized to explain nitrate leaching events. Since Frank (2005) reports that a 50% reduction in added fertilizer effectively eliminates nitrate leaching potential, we believe the ISNT may serve as an appropriate test to assist superintendents in reducing nitrate leaching from golf courses.

Summary Points

- Laboratory experiments have showed that the Illinois Soil Nitrogen Test value can be correlated to the amount of potentially mineralizing nitrogen in the soil.
- Our field studies suggest that the relationship between amino sugar-N and response of turfgrass to added fertilizer nitrogen is not as consistent as what has been reported in production agriculture. Additional studies are being conducted to analyze if a relationship between amino sugar-N levels and turfgrass fertility response exists.
- Analysis of soils gathered from lysimeters at Michigan State University from 2000-2010 will determine if the ISNT has any utility for predicting soils with the potential to leach nitrate due to fertilizer nitrogen.

We have conducted several experiments during 2010 and 2011 to investigate the yield response of turfgrass (clipping yields, as well as quality and color responses) to added nitrogen in soils with various amino sugar-N levels. Results of these trials suggest turfgrass response to added nitrogen may be lower on soils with higher amino sugar-N levels. However, the results are not as conclusive as what has been found in production agriculture.

Part of our hypothesis is that as amino sugar-N levels increase in soil, the N needs of the turf are increasingly met by mineralized organic N. Therefore, on high amino-N soils there may be an increased chance that added fertilizer nitrogen would be more susceptible to leaching. If true, then the ISNT may be useful as a tool to identify sites that are prone to contribute to nitrate contamination of groundwater due to added fertilizer. In order to test this hypothesis, soil samples have been gathered from microplot lysimeters at Michigan State University for the years 2000-2010. Our goal with the analysis of these samples is to determine if the nitrate leaching events observed on the lysimeters at Michigan State can be correlated to changes in the amino-nitrogen level in the soil.
